Abstract: This paper investigates the oil–gas relationship from a multi-scale perspective by combining the connectedness network framework and the ensemble empirical mode decomposition (EEMD) method. The empirical results show that the direction and magnitude of the information flow between oil and gas returns behave differently across time scales. In general, WTI and its refinery products tend to act as net information transmitters, while the United States and United Kingdom natural gas markets act as net receivers. The total spillover connectedness for the oil and gas markets, as measured by a rolling-window approach, has dynamic, volatile characteristics. The robustness of the results is shown by substituting Brent for WTI.

Keywords: EEMD; generalised variance decomposition; connectedness; information flow; oil–gas relationship

1. Introduction

The integration and separation of oil and natural gas prices recently has become a hot topic in market research. Natural gas prices traditionally are priced by indexing to oil prices. Although the underlying mechanism of natural gas pricing in North America is shifting from the oil price index to gas-on-gas competition, European and Asian regional natural gas prices are still primarily based on the oil index. According to the most recent report from the International Gas Union (IGU, 2017), 20% of
