This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- Two theoretical models to predict initial peak stress and plateau stress of five-layered and seven-layered corrugated paperboards respectively under the longitudinal compression.
- The presented model for initial peak stress can be obtained by analyzing the elastic buckling of board walls, which can be helpful for optimizing the structure of multi-layered corrugated paperboard.
- The model of the plateau stress is developed based on the energy conservation principle, which helps to characterize the energy-absorption properties of multi-layered corrugated paperboard in an actual logistic environment.
- Experiments are carried out to corroborate the presented model by comparing the predicted value with that by experiments, showing overall good agreement.
