Article history: Received 6 February 2016 Received in revised form 29 March 2016 Accepted 30 March 2016 Available online 2 April 2016

*Keywords: Sarcandra glabra* Sesquiterpenoids Linderanes Eudesmanes Nitric oxide

#### ABSTRACT

Five new sesquiterpenoids, including two linderanes (1–2) and three eudesmanes (3–5) were isolated from the seeds of *Sarcandra glabra*. Their structures and relative configurations were established by spectroscopic data analysis. **1** was a rare linderane derivative having an 18-membered triester ring which is a common characteristic in linderane dimers. Compounds 1–5 were investigated for their inhibitory effects on NO production in LPS-induced macrophages and **1** showed moderate bioactivity.

#### 1. Introduction

The whole plant of Sarcandra glabra (Thunb.) Nakai (Chloranthaceae) has been used as a Traditional Chinese Medicine (TCM) for the treatment of inflammation and traumatic injuries in China for thousands of years [1]. Modern pharmacological research has also confirmed the traditional applications and curative effects of S. glabra recorded in the ancient books on TCMs [2]. However, there are only a few chemical investigations on the bioactive compounds responsible for the pharmacological effects in S. glabra. Sesquiterpenoids, linderanes and eudesmanes mostly, are reported to be the most important metabolites in *S. glabra* [2–3]. Particularly, linderane dimers isolated from S. glabra and other plants of the Chloranthaceae family, have attracted a lot more attention of medicinal chemists due to their complex structures and significant bioactivities [4–7]. For instance, some linderane dimers with novel structures and anti-inflammatory activities were isolated from S. glabra in our previous research [8]. In the subsequent investigation of sesquiterpenoids in S. glabra, five new sesquiterpenoid monomers, including two linderanes (1-2) and three eudesmanes (3-5) were isolated from the seeds of S. glabra. Compound 1, named as sarglabolide L, was a rare linderane derivative having an 18-membered triester ring

which is common in linderane dimers [2–3], and also exhibited moderate inhibitory effect on NO production in LPS-induced macrophages. Herein, we report the isolation, structural elucidation and bioassay of the new compounds.

#### 2. Experimental

#### 2.1. General

Optical rotations were measured on a IASCO P-1020 polarimeter. HRESIMS experiments were performed using an Agilent UPLC-Q-TOF-MS (6520B) spectrometer. UV and IR spectra were recorded on a Shimadzu UV-2450 spectrometer and a Bruker Tensor 27 spectrometer, respectively. NMR spectra were recorded in CDCl<sub>3</sub> or CD<sub>3</sub>OD on a Bruker AV-500 NMR instrument at 500 MHz (<sup>1</sup>H) and 125 MHz (<sup>13</sup>C). Silica gel (Qingdao Marine Chemical Co., Ltd., China), ODS (FuJi, Japan), MCI gel (Mitsubishi Chemical, Japan), and Sephadex LH-20 (Pharmacia, Sweden) were employed for separation by column chromatography. MPLC was carried out on a Quiksep system (H&E Co., Ltd., China). Preparative HPLC was performed on a Shimadzu LC-6A instrument with a SPD-10A detector and a shim-pack RP-C18 column ( $20 \times 200$  mm, 10 µm). Analytical HPLC was performed on an Agilent 1200 series instrument using a DAD detector and a shim-pack VP-ODS column  $(150 \times 4.6 \text{ mm}, 5 \text{ }\mu\text{m})$ . Authentic L- and D-malic acid samples were purchased from J&K Chemical Ltd., (China). All solvents and reagents were of analytical grade.

<sup>b</sup> Recorded in CD<sub>3</sub>OD.

#### 2.2. Plant material

The fresh seeds of *S. glabra* were collected in Ganzhou, Jiangxi province, PR China in November 2013. The plant material was authenticated by Prof. Mian Zhang, Department of Medicinal Plants, China Pharmaceutical University. A voucher specimen, (No. CSH201311) was deposited in the Department of Natural Medicinal Chemistry, China Pharmaceutical University.

#### 2.3. Extraction and isolation

The fresh seeds of *S. glabra* (10 kg) were air dried and roughly ground. The ground seeds were then extracted with 95% EtOH (3 L) under reflux  $(4 \times 2 h)$  and the solvent was removed under reduced pressure to afford a brown and odorous crude extract (460 g). This extract was suspended in 2.0 L water and successively extracted with petroleum ether (4 × 2 L) and ethyl acetate (3 × 2 L).

The ethyl acetate extract (70 g) was subjected to a silica gel column and eluted with  $CH_2Cl_2/MeOH$  (50:1, 25:1, 10:1, 0:1, v/v), affording four fractions (Fr. 1–4). Fr. 2 (27 g) was further applied to a silica gel column eluted with a continuous gradient of petroleum ether/acetone (3:1 to 1:1, v/v) to afford 30 subfractions (Fr. 2.1–30). Frs. 2.1–15 were combined and chromatographed on an MCI gel column eluted with 60%, 80% and 100% methanol. The 60% methanol eluate was further separated on a reversed-phase MPLC and Sephadex LH-20 gel columns, and purified by preparative HPLC to obtain **1** (2.1 mg) and **5** (3.0 mg). Frs. 2.19–26 were combined and subjected to an MCI gel column eluted with 60%, 80% and 100% methanol. The 60% methanol eluate was further applied to a Sephadex LH-20 gel column, and purified by preparative HPLC to afford **3** (15.2 mg) and **4** (6.6 mg). Fr. 3 (12 g) was also subjected to an MCI gel column and eluted with 40%, 60%, 80% and 100% methanol to afford fractions Fr. 3.1–4. Fr. 3.2 was further chromatographed on an ODS column and purified by preparative HPLC to afford **2** (10.5 mg).
