## Keywords:

Thermal lattice Boltzmann method  
Three-dimensional finned natural convection  
Steady and transient simulations  
Differentially heated cubical enclosure  
Evaluation of the different forcing and conjugate heat transfer schemes

## ABSTRACT

In the present paper, for the first time, the lattice Boltzmann (LB) simulation of the three-dimensional steady and transient natural convection problem in a differentially heated cubical enclosure with a conducting fin on its hot wall is performed. As such, two main variants associated with the thermal lattice Boltzmann simulation of the finned natural convection problems namely, three popular forcing and two widely used conjugate heat transfer schemes are assessed for the Rayleigh numbers  $10^3$ ,  $10^4$ , and  $10^5$ . The results of the different forcing and conjugate heat transfer schemes are compared against each other and against those of the conventional methods to find the most computationally efficient schemes.

## 1. Introduction

Three-dimensional (3D) natural convection heat transfer in differentially heated cubical enclosures with conducting fins attached to their active walls has many industrial applications including energy storage systems, thermal control of electronic devices, cooling of radioactive waste containers, and ventilation of rooms, to name a few. In these applications, rectangular parallelepiped fins are widely used to augment heat transfer because of their simplicity and lower cost.

All the above-mentioned industrial applications of the natural convection heat transfer are associated with 3D phenomena. However, less effort in the literature has been devoted to the 3D numerical simulation of those problems, and majority of available studies including most recently published works have invoked 2D geometries [1–7]. Noteworthy is the fact that invoking the 2D geometries puts limits on using wide ranges of the fin geometries, thereby obstructing the way of full numerical exploration of heat transfer enhancement possibilities which could be achieved by the fins [8].

From those studies in the literature which considered the 3D problems, da Silva and Gosselin [9] used the finite element method to numerically simulate the thermal performance of an internally finned 3D cubical enclosure, to find ranges of parameters where the amount of heat transfer enhancement was affected by the fin geometry. Fredrick and Moraga [8] employed the finite volume method to perform a numerical simulation of the laminar 3D natural convection of air in a cubical enclosure with a conducting rectangular parallelepiped fin on the hot wall. As another research, Fredrick [2] used the finite volume method to conduct a 3D numerical simulation of the natural convection problem in a cubical enclosure with a vertical rectangular parallelepiped fin attached to the hot wall.

**Nomenclature**

$f_i$	Density distribution function
$f_i^{eq}$	Equilibrium distribution function of $f_i$
$g_i$	Fluid internal energy distribution function
$g_i^{eq}$	Equilibrium distribution function of $g_i$
$g_{si}$	Solid internal energy distribution function
$g_{si}^{eq}$	Equilibrium distribution function of $g_{si}$
$H$	Cubical enclosure side (m)
$k_f$	Fluid thermal conductivity (W/mk)
$k_s$	Solid thermal conductivity (W/mk)
$Nu$	Average Nusselt number
$Pr$	Prandtl number
$R$	Gas constant ( $\frac{kJ}{kgK}$ )
$Ra$	Rayleigh number (defined by Eq. (10))
$T_c$	Temperature of the cold wall of the enclosure (K)
$T_f$	Fluid temperature (K)
$T_h$	Temperature of the hot wall of the enclosure (K)
$T_o$	Average temperature in the enclosure (K), $T_o = (T_c + T_h) / 2$
$T_s$	Solid temperature (K)
$\mathbf{V} = (u, v, w)$	Velocity vector (m/s)
$x, y, z$	Cartesian coordinates (m)
$x^*, y^*, z^*$	Non-dimensional coordinates, $(x^*, y^*, z^*) = (x, y, z) / H$

**Greek symbols**

$\alpha$	Thermal diffusivity (m <sup>2</sup> /s)
$\delta x$	Lattice step (m)
$\delta t$	Time step (s)
$\varepsilon$	Internal energy density, $\varepsilon = 3/2RT$ , ( $\frac{kJ}{kg}$ )
$\lambda$	Solid–fluid thermal conductivity ratio, $\frac{k_s}{k_f}$
$\nu_f$	Fluid kinematic viscosity (m <sup>2</sup> /s)
$\rho$	Fluid density (kg/m <sup>3</sup> )
$(\rho c_p)_f$	Fluid volumetric heat capacity (J/K m <sup>3</sup> )
$(\rho c_p)_s$	Solid volumetric heat capacity (J/K m <sup>3</sup> )
$\tau_v$	Fluid hydrodynamic non-dimensional relaxation time
$\tau_g$	Fluid energy non-dimensional relaxation time
$\tau_{gs}$	Solid non-dimensional energy relaxation time

**Subscripts**

$f$	Fluid phase
$s$	Solid phase

It should be mentioned that this lack of the 3D studies in the literature could be attributed to the high computational cost associated with the 3D numerical simulations of the finned natural convection problems. This high computational cost, itself is linked not only to complex geometries of those problems but also to non-linear and coupled nature of the governing equations as well as to complexity of conjugate thermal boundary conditions at solid–fluid conjugate boundaries.

Nonetheless, the conventional numerical methods were used in all of the above-mentioned researches. However, during the last two decades, the lattice Boltzmann method (LBM) has become a robust numerical tool for fluid flow and heat transfer simulations [10–13]. This is because of its inherent features including but not limited to linear nature of the convection term, ease of coding, ease of parallelization of the computational code, and pure local collision operator [10]. Even though the early thermal lattice Boltzmann schemes such as multi-speed, suffered from severe numerical instability [11], a two-distribution function model proposed by He et al. [11], significantly improved the numerical stability of the thermal lattice Boltzmann models. Based on the proposed model by He et al. [11], a simplified 3D thermal lattice Boltzmann model was presented by Peng et al. [12], in which, the compression work and viscous heat dissipation were neglected for incompressible flows.
