5 Abstract:

6 Mars atmospheric entry is a key phase to actualize Mars pinpoint landing. In this phase, parameters including
7 atmospheric density, ballistic coefficient and lift-to-drag ratio (LDR) are uncertain for the reason of environmental
8 complexity. Ignoring these uncertainties may probably cause negative effects on the navigation accuracy. Based
9 on the desensitized unscented Kalman filter (DUKF), which obtains the state estimation by minimizing a cost
10 function involving the trace of posterior covariance matrix and the weighted norm of the posterior state estimation
11 error sensitivities, this paper further introduces parameter uncertainties into the radio beacons/inertial measurement
12 unit (IMU) integrated navigation scheme, and establishes a robust integrated navigation for Mars atmospheric
13 entry with parameter uncertainties. Numerical simulation results show that the robust navigation algorithm based
14 on the DUKF effectively reduces the influence of parameter uncertainties and illustrates a better performance than
15 traditional methods.

18 filter

19 20 1. Introduction

21 Mars exploration is an important part of human deep space explorations. An increasing number of countries and
22 international organizations have been focusing on relative technologies, especially the Mars pinpoint landing
23 activities with a landing accuracy within 100m to the target [1,2]. As the longest and extremely dangerous phase
24 during the complete landing process, Mars atmospheric entry is of key importance to actualize the pinpoint landing
25 [3-5]. Therefore, it has become a hot international research issue to improve the navigation accuracy during this
26 phase, and the literature has mainly relies on advanced navigation, guidance, and control techniques [6,7].

27 Mars atmospheric entry navigation algorithm normally consists of the dynamic model, the measurement model
28 and the Kalman filter [8]. The dynamic model is utilized to simulate force conditions of the vehicle in the real
