

# The roots of intimate partner violence

David S Chester<sup>1</sup> and C Nathan DeWall<sup>2</sup>

Intimate partner violence (IPV) is a paradoxical combination of affection and aggression. So why do people show an all-too-frequent tendency to harm their loved ones? Towards answering this question, we review a broad literature that explicates the ultimate and proximate roots of IPV perpetration. At the ultimate level, IPV perpetration is likely to be the result of evolutionary and socio-structural forces. Theories of aggression are then brought to bear in order to articulate the proximal sequence of psychological processes that magnify and constrain IPV. Interpersonal (e.g., rejection), intrapersonal (e.g., self-regulation), and biological (e.g., testosterone) factors are discussed in their relation to IPV perpetration. Finally, potentially fruitful avenues for intervention are evaluated, as exemplars of the hope that a robust understanding IPV perpetration will lead to the reduction of this costly behavior.

Sometimes people hurt strangers. Indeed, victims of aggression tend to be those who we perceive as different from ourselves [1]. Yet people also occasionally hurt others they love. This phenomenon—*intimate partner violence (IPV)*—refers to when people attempt to harm or control their current or former romantic partners against their will. IPV usually falls into four categories: physical violence, psychological aggression, sexual violence, and stalking [2]. Why might people try to harm those closest to them, whose relationship is characterized by loving affection? In what follows, we shed light on this puzzling phenomenon by reviewing the literature on the theoretical, social, and biological underpinnings of IPV.

## Prevalence

IPV occurs at staggering rates. In the U.S., approximately 22–35% of women and 7–29% of men have experienced

some form of violent or stalking behavior from their intimate partner [2]. These prevalence statistics match worldwide rates of IPV [3]. When it comes to perpetration of IPV, men and women tend to show equivalent rates, yet women are more likely to experience physical injury and to use IPV in self-defense [3]. Beyond self-defense, why does IPV occur?

## Ultimate explanations

IPV has a long history. Indeed, IPV has roots in both evolutionary and cultural forces. In the context of evolutionary processes, IPV may have evolved because it facilitated survival goals (e.g., self-defense) and reproductive goals such as preventing mates from defecting to other potential partners, committing sexual infidelity, or to help reacquire former mates [4]. The reproductive benefits that IPV yielded may have ingrained such tendencies in our species' genetic code. In contrast, feminist scholars have proposed that IPV arose out of a structural, patriarchal system, in which men seek to dominate and subdue women [5]. Moreover, socio-cultural forces (e.g., norms) may glorify and engender violent tendencies that result in IPV. These perspectives are not mutually exclusive; IPV likely results from a confluence of evolved and socially-constructed processes. These ultimate explanations for IPV are critical, yet more proximate explanations for IPV have also been substantially articulated. The following sections review these proximal explanations of IPV.

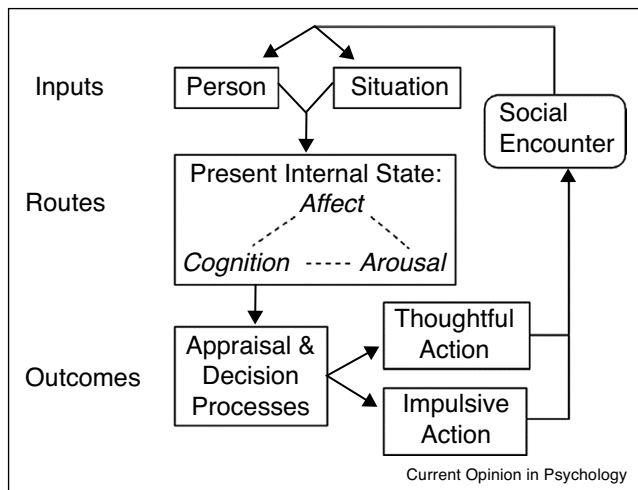

## Theories of aggression: shedding light on IPV

Many theories have been constructed in an effort to explain the complex and costly act of human aggression. These perspectives have been synthesized into two meta-theories of aggression: the General Aggression Model [6<sup>•</sup>,7] and the I<sup>3</sup> Model [8<sup>•</sup>,9].

### General Aggression Model (GAM)

The GAM details a temporal sequence of processes that explain whether an individual will act aggressively or not at a given moment (Figure 1) [6<sup>•</sup>,7]. According to this model, person (e.g., genotype) and situation (e.g., alcohol) factors act as inputs. These inputs then affect the individual's internal state (i.e., their affect, arousal, and cognition), which provides the bottom-up motivation for aggressive acts. This present state then feeds into top-down, self-regulatory processes that determine whether an individual's subsequent behavior is impulsively aggressive or thoughtfully non-aggressive. Whether the individual chooses to act aggressively or not feeds back into the situation and person inputs, which influences the likelihood of future aggression.

Figure 1

The General Aggression Model.

The GAM allows for substantial insights into the underlying, proximal motivations behind IPV perpetration [10]. A host of person and situation factors (summarized later in this review) have been implicated in IPV perpetration. Further, present internal state variables such as angry arousal and hostile cognition have also been linked to greater IPV perpetration [11] and self-regulatory processes are associated with lower IPV perpetration [12]. The fact that IPV perpetration is cyclical, with one act predisposing IPV perpetrators toward another [13], lends further evidence for the applicability of the GAM to acts of IPV. The GAM provides a coherent framework for these various processes.

### I<sup>3</sup> Model

Whereas the GAM was constructed with general acts of aggression in mind, the I<sup>3</sup> Model was constructed to attempt to better understand IPV specifically [8<sup>\*\*</sup>,11,14]. This approach posits that aggressive acts such as IPV occur due to a combination of *impellance*, *instigation*, and *inhibition*. Impellance refers to any person or situation factor (as in the GAM) that magnifies the likelihood of an aggressive act (e.g., aggressive personality traits). Instigation refers to any such factor that incites an urge to act aggressively (e.g., insults), and inhibition refers to factors that reduce the likelihood of an aggressive act (e.g., the presence of a police officer). The probability of IPV is highest when a ‘perfect storm’ occurs, in which impellance is high, instigation is high, and inhibition is low [8<sup>\*\*</sup>]. Supporting the utility and veridicality of this approach, IPV perpetration was greatest among individuals high in trait aggressiveness, who had just been provoked, and who had low self-regulatory resources [14].

IPV perpetration is undoubtedly a complex phenomenon, yet the General Aggression and I<sup>3</sup> Models can distill this

complexity into well-articulated processes that suggest novel avenues for hypothesis-testing and intervention. However, both of these models are broad, by design, and thus we now delve into specific inputs, routes, and factors that are well-established predictors of IPV.

### Interpersonal factors underlying IPV

Given that humans are social beings and that IPV is a social process, it is no surprise that interpersonal factors are some of the most potent causes of aggression between romantic partners.

#### De-humanization

IPV disproportionately harms women, and women are often seen less as people and more as sex objects, which has implications for violent behavior directed toward them [15]. The extent to which men objectify women is positively associated with their IPV tendencies toward those women [16].

#### Infidelity

Often, romantic relationships are predicated on sexual and intimate exclusivity. When partners commit sexual or romantic infidelity, IPV often ensues. IPV appears to be both a punishment inflicted on partners for their infidelity [17], as well as a deterrent for potential future infidelity [18].

#### Rejection (and other provocations)

People desire close and meaningful bonds with others [19], particularly their romantic partner. Yet partners often reject, exclude, and ostracize each other. Experiments in which participants are rejected by their romantic partners increase aggressive behavior toward their romantic partner [12]. A potential explanation for this rejection-IPV link is the finding that social rejection is painful and that this social pain has been linked to greater aggressive retaliation [20].

Other forms of antagonistic social interactions, such as insults and provocations are also reliable elicitors of IPV [11]. The social causes and consequences of IPV continue to change as social interactions more frequently occur in virtual environments. Research is needed on this burgeoning venue where IPV may be occurring at rates and in forms of which we are unaware. Although interpersonal factors aid understanding of the causes of IPV, intrapersonal factors (*i.e.*, psychological processes occurring within an individual) also help explain IPV perpetration.

### Intrapersonal factors underlying IPV

#### Psychopathology

Perpetrators of IPV often display symptoms of various forms of psychopathology. Antisocial and borderline personality disorders are associated with IPV, though for seemingly different reasons [21]. Antisocial perpetrators use IPV both proactively (in the absence of provocation) and reactively (in response to provocations), whereas
