8 **Abstract**

9 Heterogeneity in geologic parameters such as permeability, porosity and formation
10 compressibility is observed in all reservoirs including the ultra-low permeability reservoirs such
11 as shales. Computing requirements for reservoir simulation of these reservoirs are extensive
12 because of the complexity in geologic model. Surrogate models have been used successfully in
13 conventional reservoirs and homogeneous low-permeability reservoirs. In this study, robust
14 surrogate models are developed to evaluate production performance from heterogeneous low-
15 permeability reservoirs. A workflow is presented to create surrogate models from any or all of
16 the properties which affect production. Methods of representing various degrees of
17 heterogeneities in permeability are considered in this paper. The surrogate models are
18 mathematical functions for important outcomes – recoveries, gas oil ratios (GOR) with respect to
19 the heterogeneous property as input. Representing productions at particular time for different
20 permeability distributions requires a unique function. Logarithmic equation for oil recovery and
21 power law equation for cumulative GOR are found to be the most appropriate functions. The
22 developed surrogate models are then utilized to forecast production for any input distribution of
23 permeability using Monte Carlo simulations. Outputs in the form of probability density functions
24 (PDF) of oil recovery and cumulative GOR are generated after statistical analysis. The
25 probabilistic output is then interpreted as deterministic time series by considering mean values
26 along with their uncertainty bands of standard deviations and 5-95% probability ranges. These
