Abstract

1 The use of radar measurements for the space time estimation of precip-
2 itation has for many decades been a central topic in hydro-meteorology. In
3 this paper we are interested specifically in daily and sub-daily extreme val-
4 ues of precipitation at gauged or ungauged locations which are important for
5 design. The purpose of the paper is to develop a methodology to combine
6 daily precipitation observations and radar measurements to estimate sub-
7 daily extremes at point locations. Radar data corrected using precipitation-
8 reflectivity relationships lead to biased estimations of extremes. Different
9 possibilities of correcting systematic errors using the daily observations are
10 investigated. Observed gauged daily amounts are interpolated to unsampled
11 points and subsequently disaggregated using the sub-daily values obtained
12 by the radar. Different corrections based on the spatial variability and the
13 subdaily entropy of scaled rainfall distributions are used to provide unbiased
14 corrections of short duration extremes. Additionally a statistical procedure
15 not based on a matching day by day correction is tested. In this last pro-
16 cedure as we are only interested in rare extremes, low to medium values of
