This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

We propose a decentralized data popularity measurement method to identify hot data cluster-wide

We describe a dynamic data replication algorithm which dynamically creates and manages replicas of hot data

We enable clients to tentatively locate the closest of such data replicas using an approximate object location method

We describe how to handle writes to dynamically replicated objects, retaining the consistency of the storage system

We develop a prototype implementation leveraging the above contributions and prove our approach with a large-scale experimental study
