Cycleanine

Bisbenzylisoquinoline alkaloid

Ovarian cancer

Semi-synthesis

Cellular uptake

Apoptosis

ABSTRACT

Our previous studies demonstrated that cycleanine, a macrocyclic bisbenzylisoquinoline (BBIQ) alkaloid, showed potent anti-ovarian cancer activity via apoptosis induction. Here, we synthesized two novel (aminoalkyl)cycleanine analogues (**2** and **3**) through a simple and efficient two-step reaction starting from cycleanine isolated from *Triclisia subcordata* Oliv. These analogues showed greater potency than the unmodified cycleanine in three human ovarian cancer cell lines. Both **2** and **3** induced apoptosis in ovarian cancer cells by activations of caspases 3/7, cleavage of PARP, increase in subG₁ cell cycle phase and in the percentage of apoptotic cells. Further confocal fluorescence microscopy analysis confirmed the cellular uptake of alkaloids in ovarian cancer cells by using the unique (alkynyl)cycleanine (**3**) via click chemistry reaction. Our results suggest that cycleanine could be a hit compound for the future development in attacking ovarian cancer.

The macrocyclic bisbenzylisoquinoline (BBIQ) alkaloids are among different large classes of alkaloids common in plant species. BBIQ alkaloids are prevalent in the families like Menispermaceae, Annonaceae, Berberidaceae, Monimiaceae and Ranunculaceae.^{1–3} The BBIQ alkaloids were reported to exhibit anti-ovarian,^{4–7} -lung,⁸ -bladder,⁹ -colorectal,¹⁰ -gallbladder carcinoma and -prostate¹¹ cancer activities.^{12,13} The use of isolated natural products as scaffolds to generate their analogues via chemical transformation is a promising and successful approach in drug discovery.^{14,15} So far, only a small number of semi-synthetic BBIQ alkaloids (e.g. tetrandrine and fanginoline analogues,^{16–19} C14-urea-tetrandrine,²⁰ cycleanine mono-N-oxides,²¹ and berbamine derivatives²²) have been made, which show potent cytotoxicity or can reverse P-glycoprotein-mediated multidrug resistance in cancer cells.^{17,23} The making of more potent cytotoxic BBIQ alkaloids with improved activities and investigation of their mechanisms of action (e.g. cellular uptake, target identification) by using the synthetic probes are desired.^{24,25} Previously, several BBIQ alkaloids were isolated from *Triclisia subcordata* Oliv. by us and they showed potent *in vitro* anti-ovarian cancer activity.^{4–6} Among them, cycleanine (**1**) is bioactive, with the highest therapeutic index and the most abundant component (1.1%).⁴ Therefore cycleanine was preferred as a hit compound for chemical modification.¹⁴ In this study, we

semi-synthesized analogues of cycleanine and evaluated their cytotoxicity, induction of apoptosis, and cellular uptake.

The semi-synthesis of cycleanine analogues was achieved via a simple two-step reaction (Scheme 1). Reaction of cycleanine (**1**) under paraformaldehyde and concentrated HCl produced the intermediate 5-chloromethylcycleanine through a Blanc chloromethylation reaction.²⁶ Without purification 5-chloromethylcycleanine reacted with dimethylamine and propargylamine via SN₂ nucleophilic substitution reaction to yield 5-[(dimethylamino)methyl]cycleanine (**2**), and 5-[(propargylamino)methyl]cycleanine (**3**), respectively (Supporting information).

Compounds **2** and **3** were purified by silica gel chromatography to a high purity (>98%) as determined by analytical high performance liquid chromatography. The structure of 5-[(dimethylamino)methyl]cycleanine (**2**) and 5-[(propargylamino)methyl]cycleanine (**3**) was confirmed on the basis of ¹H NMR (Table S1, Figs. S1 and S2), ¹³C NMR (Table S2), 2D NMR and high resolution liquid chromatography mass spectrometric (LC-MS) analysis. The symmetry of cycleanine was lost after the chemical modification, as evidenced by that the single peak for H-5 or 5' in the ¹H NMR of cycleanine⁴ was shifted and other peaks for aromatic protons were split into two pairs of peaks (Table S1, Figs. S1 and S2). The resulting single peak around 6.80 ppm in the ¹H NMR of **2** or **3** corresponds to only one proton (H-5') which indicates the substitution at C-5 of cycleanine (**1**) by the alkylamino groups. The addition of aminoalkyl group to cycleanine could improve its water

Scheme 1. Semi-synthesis of (aminoalkyl)cycleanine analogues via modification of cycleanine. Reagents and conditions: (a) paraformaldehyde, conc. HCl, 0 °C, 3 h; (b) CH₃CN, NaOH, dimethylamine or propargylamine, rt, 3 h.

Table 1

The IC₅₀ of cycleanine (**1**), 5-[(dimethylamino)methyl]cycleanine (**2**) and 5-[(propargylamino) methyl]cycleanine (**3**) in ovarian cancer cells. Data represented as mean ± SEM (n = 5). SI means selectivity index. The SI values are calculated by comparing the activity against the non-cancer HOE cell line with those against OVCAR-8, A2780 and IGROV-1 ovarian cancer cells.

Compound	Ovarian cancer cell lines (μM)			HOE (μM)
	OVCAR-8	A2780	IGROV-1	
1	10 ± 0.6	7.6 ± 0.7	14 ± 1.0	35 ± 1.0
SI (1)	3	5	3	
2	5.2 ± 0.6	3.6 ± 0.5	4.4 ± 0.1	10 ± 0.2
SI (2)	2	3	2	
3	5.6 ± 0.2	6.3 ± 0.6	6.1 ± 0.5	32 ± 1.6
SI (3)	6	5	5	
Carboplatin	16 ± 1.0	8.0 ± 0.7	12 ± 0.9	–

solubility as found in the approved anticancer drug such as (aminoalkyl)camptothecin (Topotecan).^{27,28}

To assay the cytotoxicity or anti-proliferative activities of **2** and **3**, the IC₅₀ of these new compounds were evaluated on different ovarian cancer cell lines (OVCAR-8, A2780 and IGROV-1) and immortalized human ovarian epithelial (HOE) cell line after treatment for 72 h using Sulforhodamine B (SRB) colorimetric assay.^{29,30} The results reveal the IC₅₀ of **2** and **3** ranging from 3.6 ± 0.5 to 5.2 ± 0.6 μM and from 5.6 ± 0.2 to 6.3 ± 0.6 μM, respectively (Table 1;

Figs. S3 and S4). The results suggest that **2** and **3**, exert about 2–3 times improved potency against three ovarian cancer cells than cycleanine (**1**) with IC₅₀ ranging from 7 to 14 μM and the approved anti-ovarian cancer drug-carboplatin with IC₅₀ ranging from 8 to 16 μM. Cycleanine (**1**) and **3** seem to be slightly more tolerant to HOE cells than compound **2**. Overall, compound **3** showed milder selectivity index (SI) than **1** and **2** (Table 1).

The effects of **2** and **3** on morphology of OVCAR-8 cancer cells were also found to be time- and concentration-dependent

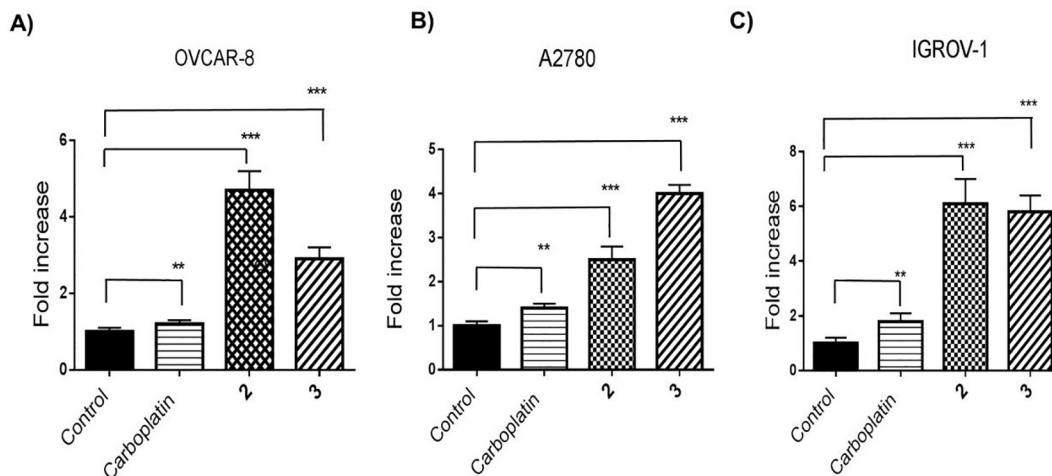

Fig. 1. The apoptotic effects (increase of caspase 3/7 activities) of carboplatin, 5-[(dimethylamino)methyl]cycleanine (**2**) and 5-[(propargylamino)methyl]cycleanine (**3**) on three ovarian cancer cell lines. Data represented as mean ± SEM, n = 6 observations, negative control was the DMSO (0.2%), carboplatin used as positive control, **2** and **3** (20 μM). Results were significant compared to control (***P < 0.001, one-way ANOVA) post hoc analysis multiple t-test compared with control (**P < 0.01, ***P < 0.001).
