This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

This contribution to the Festschrift for Professor Jing Zhu concentrates on *in-situ* electron microscopy, a topic which is key in her scientific work. In particular this paper delineates the possibilities of utilizing *in-situ* transmission electron microscopy to unravel size effects in the structure-property relationship. The focus is on metallic glasses.

Unpublished results are highlighted as:

- A unique increase in strength and strain hardening was observed for smaller sized specimens in tension which is different compared to compression experiments in in-situ TEM with the same MG compositions;
- Under cyclic loading a very interesting new phenomenon was observed and explained of increasing toughness depending on the number of cycles and size;
- The proposed experimental in-situ technique of loading and unloading cycles opens a new route to increase the ductility of metallic glasses.
