Immune system

ABSTRACT

Platelets have significant role in modulating clot formation. Additionally, emerging data indicates that platelets have considerable roles in inflammation and immune response. Platelets gather at the damaged cite and adhere to white blood cells. Subsequently, they release cytokines and chemokines which are chemotactic for neutrophils and monocytes. Therefore, platelets are necessary for targeting lymphocytes, neutrophils and monocytes to inflammation site. Those interactions enhance inflammation. Moreover, platelets serve as an immune cell by engulfing microbes. Presence of platelets affect prognosis in some bacterial or viral infection and several other diseases.

Introduction

Platelets are anucleated discoid shape hematopoietic cells which have considerable roles in modulating hemostasis. Recent studies indicate that platelets are also involved in inflammation, infection, host response and even cancer. Platelets express and secrete adhesion molecules to accumulate in damaged sites. Adhesion molecules favor adhesion of platelets to leukocytes and granulocytes. Furthermore, platelets secrete immune modulators which are chemotactic for neutrophils, monocytes and lymphocytes. Those interaction results in formation of platelet-granulocyte or platelet-leukocyte aggregates which triggers further inflammation.[1–3] Platelets are also involved in natural immunity because they can capture and engulf microbes. In addition; they prevent dissemination of bacteria by clot formation.[3,4]

Granules

Platelets are small fragments of megakaryocytes. There are 150–400.000 platelets per microliter of blood. Each of them contain three types of granules: alpha [chemokines such as: CXCL7, CXCL4 (PF4), CXCL1 (GROa), CXCL5, CCL5 (RANTES), CCL3 (MIP1a), coagulation factors, Platelet-derived growth factor receptors (PDGF), Transforming growth factor beta (TGF-b), P-selectin, fibrinogen, vWF, fibronectin,], dense (calcium, magnesium, nucleotides (ADP,ATP), serotonin, histamine) and lysosomal [gylcohydrolase, proteases (cathepsin, asid phospatase,colagenase, elastase)] granules.[5] P-selectin is an α-granule derived mediator which facilitates rolling and tethering of leukocyte and adhesion of leukocytes to endothelium following to activation of platelets. Dense bodies induce vasoconstriction, production of pro-inflammatory cytokines and modulation of inflammation.[6] Dense granules contains high amount of serotonin. Recent research reveals that recruitment of neutrophils is promoted by platelet derived serotonin in acute inflammation.[7] Ions such as Ca and Mg probably effects signal transduction during all those interactions. Some enzymes (e.g. cathepsin) of lysosomal granules nonspecifically breakdown microbe so they are classified as first line defenders of immunity.[3]

Pro-inflammatory cytokines are released in inflammation and accepted as one of the key regulatory of inflammation. Those cytokines can be secreted from different cell types, have different targets and activate different pathways. Interleukin-1 (IL-1) is an important cytokine secreted mostly by monocytes and macrophages that stimulate acute phase reactants, fever and adhesion molecules. Evidence indicates that platelets secrete IL-1 as well.[8] Activated platelets induce dendritic cells (DC) to release immunoregulatory cytokine IL-10.[9] In addition; platelets can stimulate monocytes which in turn secrete Interleukin-8.[10]

Chemokines

Granules of thrombocytes contain chemokines produced by megakaryocytes. RANTES (regulated on activation, normal T

cell expressed and secreted, also known as CCL5) is a CC chemokine family member. Monocytes tether to endothelium via P-selectin and this induce platelet derived RANTES release. Thereby, recruitment of further monocytes from circulation is triggered.[10,11] Platelet derived RANTES has also immune-modulator affect. RANTES enhance cytotoxic ability of CD8 T-helper cells and cytokine production in CD8 T-cells.[12] Furthermore, RANTES mRNA expression increases after platelet interacts with B-cells and IgG synthesis from differentiated B-cells is promoted[13] CXC chemokines such as IL-8, neutrophil-activating peptide-2 (NAP-2) coordinates recruitment and activation of neutrophils.[14,15] Beta-thromboglobulin (β-TG), platelet factor 4 (PF4) are also CXC class chemokines that are chemotactic for neutrophils. PF4 induces differentiation of monocyte to macrophages and augment monocyte survival.[16] PF4 can directly kill intra erythrocytic parasites after contact with parasitized cells.[17] Thus, platelets might be accepted as natural anti-parasitic. Moreover, platelet derived RANTES and PF4 augment surface monocyte arrest. As a summary, platelets are necessary for targeting lymphocytes, neutrophils and monocytes to inflammation site.A chemokine derived peptide; "Thrombocidin" which is antibacterial and antifungal is stored in α-granules Thus, platelets has an impact on innate immune system.[18,19]

Pattern recognition receptor

Membrane of a platelet is covered by a great number of receptors such as transmembrane, pattern recognition and FcR receptors that are stimulated by paracrine, exocrine and autocrine signaling. Toll like Receptors (TLR) are members of pattern recognition receptor family. Recent researches confirm that there is expression of TLR1, TLR2, TLR4, TLR6, TLR9, TLR7 and TLR9on platelets. They are activated upon interaction with a stimulator like viruses, microbes or other hematopoietic cells.[20–24] Encephalomyocarditis virus (EMCV) activates the platelet-TLR7 receptor. Subsequently, thrombocytopenia is observed because platelet interacts with leukocytes and forms aggregates following to internalization of neutrophils. Therefore, platelets-TLR7 is important in host survival.[20] TLR2 recognizes bacteria. Stimulation of TLR2 amplifies P-selectin expression, enhances pro-inflammatory response of platelet and increases formation of platelet-neutrophil aggregation.[24] TLR4 enhances bacterial trapping by stimulating formation of neutrophil extracellular trapping (NETs).[23] TLR4 activation by bacterial LPS causes formation of platelet-granulocyte aggregates.[25] Platelets also present bacteria to neurophils via toll TLR.[2]

CLEC-2 (C-type lectin-like receptor) is a kind of ITAM receptor (also known as tyrosine kinase-dependent platelet activation receptor) which is expressed on T cells, platelets, DC and probably other hematopoietic cells. It is also expressed on platelets. Podoplanin (also known as Gp38) is potent ligand for celec-2 receptor and found in lymphatic endothelial cells. CLEC2-podoplanin interaction is important in separation of blood-lymphatic during embryogenesis, proliferation of lymphatic cells, development of lymph nodes, recruitment of lymphocyte in long-term. Briefly it influences development of tissues of immune system and immune response.[26,27] On the other hand, CLEC-2 receptors of platelets bind podolomin expressing tumor cells which is considered as one of the metastasis mechanism.[28]

CD40L (also known as CD154 a member of TNF (Tumor Necrosis Factor) family) is found in platelets and its receptor is CD40 which is described on many cell types including B-cells and antigen presenting cells. CD40-CD40L interaction contributes to binding of platelets to monocytes, macrophages, DCs and lymphocytes. That interaction induce several immune and inflammatory response such as production of superoxide and reactive oxygen species (ROS) in neutrophils, production of antigen specific IgG, activation of B cells, switching of B cell isotype, priming of T cell, formation of germinal center, activation of macrophages, maturation of DC and enhancing cytotoxic T–cell response.[1,13,29–32]

Complement system induces platelets and vice versa. It has been known for a long time that complement system promotes thrombus formation by activating platelets. However, emerging studies indicates platelets also activate the complement system through P-selectin–C3B interaction.[33] Platelets have also receptors for C1Q which has a role in classic pathway.[34]

Membrane glyocoproteins function as receptors so are involved in adhesion. Leukocyte recruitment after an injury depends on interaction of A mb2 (Mac-1) integrin of leukocytes and glycoprotein (GP) Ib-a of platelets.[35]

Platelets express high affinity IgE receptor (FcepsilonRI) on their cell membrane. Stimulation of FcepsilonRI receptor triggers release of serotonin and RANTES and subsequently promotes IgE mediated allergic reaction.[36]

Adhesion molecules

Adhesion molecules are secreted from α-granules of platelets and they are quite important in thrombus formation. As it is mentioned before, P-selectin is a type of adhesion molecule is secreted from α-granules. Main function of P-selectin is mediating rolling and tethering through adhesion. However, recent researches reveal the key stone role of P-selectin in platelet mediated inflamation. P selectin interacts with those expressing PSGL1 (P selectin glycol protein) such as neutrophils, monocytes, DC, endothelial cells and other activated platelets. P-selectin-PSGL1 interaction results in production of superoxide anion radicals in macrophages and monocytes, stimulation of neutrophil rolling, transendothelial migration and leukocytes integrin activation. Furthermore, cell adhesion via P-selectin regulates gene expression in leukocytes. Generation of dentritic like cells from monocytes by P-selectin stimulation is seen experimentally. As a result, DC might present antigens captured by platelets due to DC-platelet interaction through P-selectin. Ultimately, disturbing P-selectin-PSGL1 interaction reduces inflammation.[2,37–43]

Experimentally, activation of TLR7 agonist enhance p-selectin expression and stimulate platelets-white blood cells (WBC) interaction.[20] Thus, we can conclude that adhesive molecules of platelets might be necessary to attract granulocytes to injured sites. Integrins are transmembrane receptors which have significant impact on platelet adhesion. Different subtypes of integrins are discovered in different cell types including hematopoetic cells (such as leukocyte and platelet), collagen and endothelial fibroblasts. β1, β2 and β3 integrins are expressed on platelets and mostly involved in adhesion of platelets to extracellular matrix and fibrinogen.[44,45]

ICAM-2 (intercellular adhesion molecule 2) is a member of Ig superfamily and the only ligand of β2 integrin presents on platelets. ICAM-2 of platelets contribute to adhesion and tethering of T cells via binding of leukocyte integrin; LFA1 (Leukocyte function antigen1).[46] In short, leukocyte-platelet interaction requires integrins.

Role of platelet in certain diseases

Even the exact reason is still uncertain; in many viral infections non-immune thrombocytopenia is observed. Thrombocytopenia may be a sign of infection, due to the fact that platelets are recruited to the site of inflammation and adhere to WBC to enhance their affect and form aggregates so the number of circulating thrombocytes decreases. Platelets could be related to prognosis of viral
