This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

**Highlights**

- An ocean forecasting system (PRO-ROMS), based on the Regional Ocean Modeling System, has been developed for the coastal area of Puerto Rico and the U.S. Virgin Islands providing a 3-day forecast of ocean currents, sea surface height, temperature and salinity.
- Modeled currents are validated at shallow depths (<100m) on top of the shelf. Surface currents from PRO-ROMS are validated with a High Frequency Radar (HFR), and sub-surface currents are validated with 4 Acoustic Doppler Current Profilers, showing a good agreement in the spatial and temporal distributions with observed quantities.
- A Taylor diagram is used to summarize PRO-ROMS model performance which shows a reduction in the root mean square error compared to the AmSeas NCOM regional model.
- 12 floating drifters were deployed in the coastal area of Puerto Rico and tracked for several days. A simple advection algorithm in which the drifters are assumed to be passive tracers shows that PRO-ROMS on average predicts the trajectory of the drifters better than AmSeas during the initial 60 hours after deployment.
