ABSTRACT

In this review the molecular structures of a series of trinuclear alkynyl and diynyl Group 11 cations $[M_3(\mu\text{-dppm})_3(X)_n]^{(3-n)+}$ ($M = \text{Cu, Ag}$; $n = 1, 2$; where X is an alkynyl or diynyl group, an inorganic anion or solvent) are considered from the points of view of (i) the dimensions and geometries of the $M_3(\text{P-P})_3$ cores, (ii) the conformations of the dppm ligands, and (iii) the attachment of the alkynyl and diynyl ligands. In the crowded $[M_3(\mu\text{-dppm})_3]^{3+}$ core, the dppm ligands are arranged so that there is always one CH₂ group up and two down, to give pseudo mirror symmetry perpendicular to the M_3 plane (crystallographic in some cases). Attachment of the alkynyl or diynyl substituent(s) occurs roughly normal to the M_3 plane; according to their perpendicularity, the C(1) atom may be μ_2 or μ_3 . In most cases where only one alkynyl or diynyl ligand is present, a second ligand is also attached to the M_3 core. Unusual and interesting dispositions/conformations of the dppm ligands are widespread, among the mono-diynyl complexes in particular, whereby some phosphorus donor atoms lie at unusual distances out of the M_3 planes, a concomitant of strong agostic interactions between phenyl H atoms and the atoms of the open M_3 face, and weak $M \cdots M$ interactions. With one X group, $\text{C-H} \cdots M$ interactions persist on the other face, with $\text{C-H} \cdots X$ interactions with the alkyne affecting the inclination of the alkyne and the conformation of the Ph rings. With two substituents (one of which may be a loosely bound anion), similar interactions may occur, accompanied by twisting of the dppm chelate ring to displace P atoms from the M_3 plane. These factors possibly inhibit formation of the bis(diynyl) complexes, which are only obtained under more strongly basic conditions.

1. Introduction

Numerous examples of trinuclear Group 11 complexes containing $M_3(\mu\text{-dppm})_3$ [$M = \text{Cu, Ag}$; $\text{dppm} = \text{CH}_2(\text{PPh}_2)_2$] moieties are known, more than 65 structural studies of which are listed in the Cambridge Structural Database (CSD). An extensive survey to 2005 of complexes $[M_3(\mu\text{-dppm})_3(\mu_3\text{-X}^1)(\mu_3\text{-X}^2)]^+$ in which X^1 , $\text{X}^2 = \text{halogen}$ or other simple anion has been given previously [1], including a summary of cation core geometries presented in Tables 1 and 2 therein. Several later individual studies have appeared [2]. A series of alkynyl- or diynyl-Group 11 complexes has been generally obtained from the reactions of $[M_2(\mu\text{-dppm})_2(\text{NCMe})_n]A_2$ ($M = \text{Cu}$, $n = 4$; Ag , $n = 2$; $A = \text{BF}_4$, PF_6) with a terminal alkyne or

diyne in the presence of an excess of KOH or dbu in refluxing $\text{CH}_2\text{Cl}_2/\text{MeOH}$ [3]. Depending on the stoichiometry and reaction conditions, either mono- or bis- μ_3 -alkynyl-Group 11 metal cluster compounds $\{[M_3(\mu\text{-dppm})_3](\text{C}\equiv\text{CR})_n\}^{(3-n)+}$ ($n = 1, 2$) may be obtained. In some cases, further reaction may occur to give bi-, tetra- or hexa-nuclear clusters [4,5], although these systems are not considered further here.

We have recently described the syntheses and properties of the diynyl complexes $\{[M_3(\mu\text{-dppm})_3](\mu\text{-C}\equiv\text{CC}\equiv\text{C}[M'L_m])_n\}^{(3-n)+}$ [$M = \text{Cu, Ag}$; $n = 1, 2$; $M'L_m = \text{Re}(\text{CO})_3(\text{Bu}^t_2\text{-bpy})$, $\text{Ru}(\text{dppe})\text{Cp}^*$ ($\text{dppe} = \text{Ph}_2\text{PCH}_2\text{CH}_2\text{PPh}_2$)], including the single-crystal X-ray structures of those derivatives with $M'L_m = \text{Ru}(\text{dppe})\text{Cp}^*$, $M = \text{Cu}$, $n = 1$ (1), 2 (2) and $M = \text{Ag}$, $n = 1$ [3 (two solvates)], and $M'L_m = \text{Re}(\text{CO})_3$
