## Abstract

Crystal structure, magnetism, martensitic transition, electronic structure and mechanical properties of Heusler compounds  $\text{Mg}_2\text{YZ}$  (Y=Sc, Ti, V, Z=Al, Ga, In) were studied by carrying out first-principles calculations based on density functional theory. All compounds in the cubic phase have an inverse Heusler structure with  $\text{Hg}_2\text{CuTi}$  as the prototype.  $\text{Mg}_2\text{ScZ}$  is paramagnetic and does not undergo a martensitic transition, while  $\text{Mg}_2\text{Ti}$  (or VZ) undergoes a martensitic transition and shows ferromagnetism, which is basically unchanged (or smaller) with the phase transition. Y and Z atoms play major and minor roles, respectively, in the electronic structure, which directly affects the magnetism of the two phases. The calculated mechanical properties indicate that  $\text{Mg}_2\text{TiZ}$  is ductile in the cubic phase and brittle in the tetragonal phase, while  $\text{Mg}_2\text{VZ}$  has a similar brittleness in both the cubic and tetragonal phases. It is predicted that  $\text{Mg}_2\text{TiZ}$  and  $\text{Mg}_2\text{VAl}$  (or Ga) are prone to tetragonal distortion, with  $\text{Mg}_2\text{VIn}$  tending towards further phase transition because of mechanical instability.

Keywords:

Heusler compound; martensitic transition; first-principles; magnesium alloy; ferromagnetism

## 1. Introduction

Heusler compounds have received considerable attention because of their rich physical properties, such as ferromagnetism [1-4], shape memory effect [5-11], half-metal [12-17] and thermoelectric [18-20] properties. Moreover, these properties can be regulated by changing the material components or ratios. At present, more than 1000 types of Heusler compounds have been found, and possible compositions for these materials have been summarized in a previous report [21]. The general formula for a Heusler compound is given as  $X_2YZ$  (full Heusler compound) or  $XYZ$  (half Heusler compound); such compounds show a high degree of order. The crystal structure of a full Heusler compound consists of four FCC sublattices, which move 1/4 of the distance along the diagonal line of the body [22,23]; the structure shows four equidistant sites, with Wyckoff positions of A(0,0,0), B(1/4,1/4,1/4), C(1/2,1/2,1/2) and D(3/4,3/4,3/4). If the valence electrons of X are higher than the valence electrons of Y, the Heusler compound crystallizes in the cubic space group  $Fm\bar{3}m$ , with  $\text{Cu}_2\text{MnAl}$  ( $L2_1$ ) as prototype with an atomic site occupation of  $X^A-Y^B-X^C-Z^D$ . Otherwise, the inverse Heusler structure is crystallized, with an atomic site occupation of  $X^A-X^B-Y^C-Z^D$  in the cubic space group  $F\bar{4}3m$ , with  $\text{Hg}_2\text{CuTi}$  ( $XA$ ) as prototype [24].

In 2016, Ogawa et al. found that Mg-20.5 at% Sc alloy in the space group  $IM\bar{3}M$  is a superelastic alloy at 120 K and that Mg-18.3 at% Sc shows an obvious shape memory effect [25]; in 2017, Natarajan et al. investigated the phase stability of binary alloy Mg-Sc using a first-principles method [26]. The atomic site occupation of the BCC Mg-Sc supercell is the same as that for the Heusler compound, which provides evidence for the possibility of investigating Mg-based Heusler compounds with a shape memory effect.

In this paper, the stability, martensitic transition, mechanical properties, magnetism and electronic structures
