This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

14 **Abstract**

15 This paper addresses a hybrid renewable system that consists of a micro-Combined Cooling
16 Heat and Power (CCHP) unit and a solar energy conversion device. In addition to a traditional
17 PV system, a High Concentrator Photovoltaic (HCPV) device, the design of which is suitable
18 for building integration application, was also modelled and embedded in the hybrid system.
19 The work identifies the optimal management strategies for the hybrid renewable system in an
20 effort to minimise the primary energy usage, the carbon dioxide emissions and the operational
21 costs for variable electricity prices that result from the day-ahead electricity market. An “ad
22 hoc” model describes the performance of the HCPV module, PV and Internal Combustion
23 Engine, whilst the other units were simulated based on their main characteristic parameters.
24 The developed algorithm was applied to three different building typologies. The results
25 indicate that the best configuration is the hybrid renewable system with PV, which can
26 provide a yearly primary energy reduction of between 20% and 30% compared to separate
27 production. The hybrid renewable system with HCPV becomes competitive with the PV
28 technology when the level of solar radiation is high.
