ABSTRACT

P-21 activated kinases, or PAKs, are serine–threonine kinases that serve a role in diverse biological functions and organ system diseases. Although PAK signaling has been the focus of many investigations, still our understanding of the role of PAK in inflammation is incomplete. This review consolidates what is known about PAK1 across several cell types, highlighting the role of PAK1 and PAK2 in inflammation in relation to NADPH oxidase activation. This review explores the physiological functions of PAK during inflammation, the role of PAK in several organ diseases with an emphasis on cardiovascular disease, and the PAK signaling pathway, including activators and targets of PAK. Also, we discuss PAK1 as a pharmacological anti-inflammatory target, explore the potentials and the limitations of the current pharmacological tools to regulate PAK1 activity during inflammation, and provide indications for future research. We conclude that a vast amount of evidence supports the idea that PAK is a central molecule in inflammatory signaling, thus making PAK1 itself a promising prospective pharmacological target.

65 1. Introduction

66 P-21 activated kinases, or PAKs, are serine–threonine kinases
 67 activated by the small GTP binding proteins Cdc42 and Rac1 [1,2], and
 68 they serve a role in diverse biological functions and organ system
 69 diseases [3]. So far, the PAK isoforms identified in mammalian cells are
 70 characterized into group I (PAK1–3) and group II (PAK4–6). The first
 71 group of PAKs shares a high sequence homology and is highly evolu-
 72 tionarily conserved [3].

73 Originally discovered in brain tissue [4], PAKs are important regula-
 74 tors of the inflammatory response. To the best of our knowledge,
 75 only PAK1 and PAK2, but not PAK3, have been thus far associated with
 76 inflammation, immunity, and infective diseases [5–9]. Additionally,
 77 PAK1 and PAK2 are the two most abundantly expressed PAK isoforms
 78 in white blood cells, including T lymphocytes, neutrophils, macro-
 79 phages, and mast cells [10–14]. One way in which PAK1 and PAK2
 80 regulate the molecular mechanisms of inflammation is through activa-
 81 tion of their downstream target nicotinamide adenine dinucleotide
 82 phosphate-oxidase (NADPH oxidase) in neutrophils [15,16]. In the
 83 above mentioned cell types, PAK1 is implicated in the regulation of
 84 NADPH oxidase activity through several direct and indirect mecha-
 85 nisms, which are described hereafter.

86 In this review, we describe the role of PAKs in inflammation, with an
 87 emphasis on PAK1 and PAK2. PAK signaling has been the focus of many
 88 investigations under many different experimental models and condi-
 89 tions. This review aims to piece together what is known about PAK1
 90 across several cell types, highlighting the role of PAK1 and PAK2 in
 91 inflammation in relation to NADPH oxidase activation. Also, we will dis-
 92 cuss the role of PAK1 as a therapeutic anti-inflammatory target, explore
 93 the potentials and the limitations of the current drugs that regulate
 94 PAK1 activity during inflammation, and provide indications for future
 95 research.

96 2. PAK structure and activation

97 P21-activated kinases are a family of enzymes that are central in
 98 regulating intracellular signaling and cellular functions [13,17,18]. The
 99 actions of PAKs in the context of different cellular functions [19] are
 100 tightly regulated and are often achieved as a result of conformational
 101 changes in PAK molecular domains. Thus, a clear knowledge of the
 102 structure of PAKs is fundamental to understand their regulation
 103 and functions. In Fig. 1, we illustrate the primary structure of PAK1,
 104 and we show one of the most studied mechanisms of its activation.

105 The entire PAK structure is incompletely understood, although the
 106 crystal structure of PAK1 has been partly resolved. So far, it is known
 107 that the N-terminus of Group I PAKs shares a unique proline-rich
 108 motif located between amino acids 182–203, which is the binding site
 109 of the SH3 domain of PIX, an essential activator of PAK1/2/3 (Fig. 1 A).
 110 Thus far, only some parts of the auto-inhibitory domain, located in the

111 N-terminal domain, and the kinase domain, located in the C-terminal
 112 domain, of some members of the PAK family have been elucidated [19].

113 One important key to understanding PAK structure and function is to
 114 understand its mechanism of activation. When in the inactive state,
 115 PAK1 homodimerizes with another PAK1 molecule through the dimer-
 116 ization segment (DI), the inhibitor switch domain (IS), the kinase-
 117 inhibiting segment (KI) domain, and an amino acid segment across
 118 the kinase domain (Fig. 1 B). The IS domain overlaps with the protein
 119 binding domain (PBD), which binds the GTPases Rac1/cdc42 and the
 120 auto-inhibitory domain (AID). The binding of GTPases to the PBD
 121 induces a conformational change in the kinase inhibitor (KI) fragment
 122 located within the AID. This is first followed by the dissociation of the
 123 IS from the kinase domain, then by PAK autophosphorylation of the
 124 T-loop, resulting in the activation of PAK1.

125 An ATP binding pocket (where ATP is the native ligand) exists and
 126 lies between the N-lobe and the C-lobe of the PAK1 kinase domain.
 127 This niche has been recently exploited to achieve pharmacological mod-
 128 ulation of PAK1. A molecular analysis of the kinase domain structure
 129 using a Q-site finder technique has illustrated that molecular niches
 130 exist that could nest small pharmacological molecules. In fact, most
 131 PAK non-native ligands (e.g. 3Q53 [20], 3FXZ [21], 3FY0 [21], and
 132 2HY8 [22]) bind to the ATP binding pocket, nurturing hopes that
 133 modulation of PAKs can be pharmacologically achieved.

134 Additional studies are required to fully understand the mechanism
 135 of PAK activation, especially across multiple organs and cell types.
 136 There remains a limited understanding of the effects of PAK regulation
 137 of the inflammatory process. A better understanding of both the role
 138 of PAK in multiple systems, as well as the relationship between the
 139 PAK structure and function, will provide the necessary knowledge to
 140 design activators or inhibitors that bind to PAK and modulate its
 141 functions in the inflammatory process.

142 3. Mechanisms of PAK activation

143 Besides activation via the small Rho GTPase Rac1, PAK1 can alterna-
 144 tively or synergistically be activated by other molecules, including
 145 membrane lipids [23] or receptor agonists [24]. Recently, we have
 146 understood that a vast number of important regulators of the inflamma-
 147 tory process act upon PAK1 as a downstream target and exert their
 148 effects through PAK1. In this section and in Fig. 2, we describe some re-
 149 cent advances in the understanding of signaling mechanisms involved
 150 in the activation of PAK during inflammation.

151 3.1. Lipid-mediated and receptor tyrosine kinase-mediated activation of 152 PAK1 and NADPH oxidase

153 Long chain sphingoid bases, sphingosine, phosphatidic acid, and
 154 phosphatidyl inositol produce stimulatory effects on PAK1 through a
 155 domain that is similar to the GTP-ase binding domain [25]. On the
