This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

## Highlights

- 29.8% of participants had been victimized in cyberbullying
- Cyberbullying victims but not bully-victims with anger ruminative tendencies and strong unjust world beliefs are more likely to experience psychiatric symptoms
- There are substantial differences between victims and bully-victims in the mechanisms underlying the victimization–psychiatric symptoms association
- Emotion regulation and just world beliefs appeared to be protective factors against psychiatric symptoms in cyberbullying victims but not bully-victims
