ABSTRACT

This study examines the role played by submission devices (mobile vs. desktop) in online travel reviewing behaviour. We analyse over 1.2 million online reviews from Booking.com and detect the presence and distinctive features of online reviews submitted by mobile devices. Our findings indicate that 1) the share of online reviews submitted by mobile increased at a very high rate over time (higher than the growth rate of those submitted by desktop); 2) there is a systematic and statistically significant difference between the features and distributions of online reviews submitted through mobile devices vs. online reviews submitted through desktops. We raise awareness of the role played by submission devices in online travel behaviour research and present implications for future research.

1. Introduction

Tourism and hospitality management scholars increasingly engage with questions related to online reviews (ORs) because of their significant impact on consumer decision-making (Fang, Ye, Kucukusta, & Law, 2016) and company performance (Yang, Park, & Hu, 2018). However, these studies fail to differentiate or control their findings for the submission device used by online reviewers. To address this gap, we examine a large sample of online hotel reviews. The purpose of this work is, first, to raise awareness regarding the relevance of the review submission device when interpreting online review-related findings. Second, the results also address the growing need to better understand online reviewing behaviours via mobile devices.

2. Mobile online reviews

ORs as a form of electronic word-of-mouth (eWOM) have been researched extensively (see Cantallops & Salvi, 2014; Kwok, Xie, & Richards, 2017 for literature reviews). Findings consistently demonstrate their prominence in travellers' decision making (Baka, 2016; Casalo, Flavian, Guinaliu, & Ekinci, 2015; Mariani, Baggio, Buhalis, & Longhi, 2014). Despite the abundance of studies that leverage ORs to understand the antecedents and consequences of eWOM in tourism and hospitality (e.g., Ayeh, Au, & Law, 2013; Banerjee & Chua, 2016; Filieri, 2016), none of them have looked in depth at the role played by the device used to submit ORs or actively questioned if and to what extent the specific communication channel used might affect eWOM behaviour and features. This is rather surprising as, from a practical point of view, consumers increasingly access the Internet through their smartphones (comScore, 2017) and, from a theoretical point of view, scholars have argued that mobile ecosystems are characterized by distinctive information capabilities and pervasiveness that affect consumer behaviour (Lurie et al., 2018).

An analysis of extant literature reveals interesting insights on how eWOM is generated and used across channels (mobiles vs. desktop). For instance, Okazaki (2009) finds that mobile users are more active in generating ORs than their desktop counterparts. Lurie, Ransbotham, and Liu (2014) find that mobile WOM is less reflective, more focused on the present, less subject to retrospective biases, more affective, less cognitive, more one-sided, more negative, and less socially oriented than desktop WOM. Moreover, after controlling for observable differences in content, mobile eWOM appears to be less valued by other consumers. Marz, Schubach, and Schumann (2017) examine how the helpfulness of mobile eWOM differs from desktop eWOM and conclude that there are significant differences in style-specific characteristics. Interestingly, they also observe that the knowledge of the type of device the reviewer used to write the review influences other consumers' evaluations of the review's helpfulness. Despite these important findings, the topic of mobile eWOM is currently missing from the tourism and hospitality literature.

3. Methodology

We deploy a data science approach (Gerard, Osinga, Lavie, & Scott,

2016; Mariani, Baggio, Fuchs & Hopken, 2018) to examining the distribution of ORs over time and across channels (mobile vs. desktop). We scraped the entire population of Booking.com ORs for hotels based in London (UK) over a two-year time frame (January 1, 2015 to December 31, 2016). Booking.com was selected as it embeds the largest number and share of certified hotel reviews worldwide (Revinate, 2017). The data scraping and analysis were carried out using a web crawler developed in Python. We obtained a total of 1,217,002 reviews across 861 hotels.

To compare ORs, we employed both conventional (Welch two samples *t*-test) and non-parametric (Mann-Whitney-Wilcoxon Test) statistical tests. We employed nonparametric kernel density estimators to test if the sub-distribution of mobile OR ratings was significantly different from that of desktop ORs. Specifically, we used the Tn-statistic proposed by Li, Maasoumi, and Racine (2009) and tests reported in Maasoumi and Racine (2002) to test if the sub-distribution was equal.

4. Findings

4.1. Submission trends

There is an increasing trend in the number of ORs submitted overall and specifically by mobile (Fig. 1). In January 2015 the number of desktop ORs was higher than the number of mobile ORs, but starting from February 2015 the situation is reversed. Over the 2 years considered, the growth rate of desktop ORs is 11.4%, increasing from 20,467 in January 2015 to 22,810 in December 2016. Mobile ORs increased by 171.3% (more than 12 times the rate of desktop ORs) from 14,624 in January 2015 to 39,687 in December 2016.

4.2. Differences in mobile vs. desktop ORs

We created two subsamples: one including all the reviews submitted by desktop (N = 532,529) and the other including the reviews submitted by mobile (N = 684,473). When comparing the subsamples, several statistically significant differences emerged (Table 1).

First, the average rating (valence) for mobile ORs (7.896) is higher than the average rating for desktop ORs (7.811). Mobile ORs are also more polar (the SD for mobile is higher than the SD for desktop). Both distributions are left-skewed. This result is consistent with previous research by Mariani and Borghi (2018). However, the distribution of mobile ORs' ratings (skewness = -0.844652) is more skewed than the distribution of desktop ORs' ratings (skewness = -0.775544) as indicated by the nonparametric kernel density estimators (Fig. 2) and the results of the nonparametric tests of equality of the distributions (Li et al., 2009).

Second, the average number of helpful votes for mobile ORs (0.182) is lower than for desktop ORs (0.224). The SD for mobile is lower than for desktop, signalling that even in the most polar cases, mobile ORs are consistently perceived as less helpful than desktop ORs.

Subsequently, we narrowed the sample to ORs with English texts (N = 475,462) and again divided it into desktop ORs (N = 201,549) and mobile ORs (N = 273,913). The findings show that 1) the average length of the text (in characters) of mobile ORs is lower than of desktop ORs; 2) using the pre-defined split into positive and negative comments provided by Booking.com, we find that both the average length of the positive section and of the negative section are lower for mobile ORs (Table 2).

Table 1

Comparison of means across sub-distributions of ORs by device.

| | Total Sample ORs (N = 1,217,002) | | Mobile ORs (N = 684,473) | | Desktop ORs (N = 532,529) | | <i>t</i> -test | Non parametric test |
|--------------------------|----------------------------------|----------------|--------------------------|----------------|---------------------------|---------------|---|--|
| | Mean | SD | Mean | SD | Mean | SD | _ | |
| Valence Helpful Votes | 7.859 0.201 | 1.743 0.677 | 7.896 0.182 | 1.774 0.638 | 7.811 0.224 | 1.70 0.723 | $t(1,166,000) = 27.023^{***}$ $t(1,067,900) = -33.169^{***}$ | W = 174570000000*** W = 185890000000*** |
