We develop finite-population asymptotic theory for covariate adjustment in randomization-based causal inference for 2<sup>K</sup> factorial designs. In particular, we confirm that both the unadjusted and the covariate-adjusted estimators of the factorial effects are asymptotically unbiased and normal, and the latter is more precise than the former.

# Covariate adjustment in randomization-based causal

#### **1. Introduction**

Randomization is often considered the gold standard for causal inference [\(Rubin,](#page--1-0) [2008\)](#page--1-0). A well-established methodology to conduct causal inference is the potential outcomes framework [\(Neyman,](#page--1-1) [1923;](#page--1-1) [Rubin,](#page--1-2) [1974\)](#page--1-2), which defines the causal effect of a binary treatment factor as the comparison between the potential outcomes under treatment and control. In the presence of multiple binary treatment factors, we can evaluate them simultaneously under the 2*<sup>K</sup>* factorial design framework [\(Fisher,](#page--1-3) [1935;](#page--1-3) [Yates,](#page--1-4) [1937\)](#page--1-4). Several researchers (e.g., [Kempthrone,](#page--1-5) [1952,](#page--1-5) [1955;](#page--1-5) [Wilk](#page--1-6) [and](#page--1-6) [Kempthrone,](#page--1-6) [1956;](#page--1-6) [Bailey,](#page--1-7) [1981,](#page--1-7) [1991;](#page--1-7) [Dasgupta](#page--1-8) [et al.,](#page--1-8) [2015\)](#page--1-8) advocated conducting randomization-based causal inference for 2<sup>K</sup> factorial designs, which has several advantages over the widely-used regression-based inference. For example, randomization-based inference is applicable to the finite-population setting, and therefore may be more reasonable in practice (e.g., [Miller,](#page--1-9) [2006;](#page--1-9) [Lu](#page--1-10) [et al.,](#page--1-10) [2015\)](#page--1-10). For more discussion on the comparison and reconciliation of randomization-based and regression-based inferences for 2*<sup>K</sup>* factorial designs, see [Lu](#page--1-11) [\(2016\)](#page--1-11).

In randomization-based causal inference, covariate adjustment [\(Cochran,](#page--1-12) [1977\)](#page--1-12) is a variance reduction technique widely used by researchers (e.g., [Deng](#page--1-13) [et al.,](#page--1-13) [2013;](#page--1-13) [Miratrix](#page--1-14) [et al.,](#page--1-14) [2013\)](#page--1-14). In an illuminating paper, [Lin](#page--1-15) [\(2013\)](#page--1-15) demonstrated the advantages of performing covariate adjustment for randomized treatment–control studies (i.e.,  $2^1$  factorial designs). However, to our best knowledge, for 2<sup>K</sup> factorial designs which are of great importance from both theoretical and practical perspectives, similar discussions appear to be absent; it is unclear whether covariate adjustment is beneficial for 2*<sup>K</sup>* factorial designs, and if so, how to quantify said benefit. In this paper we answer this question, by extending the discussions in [Lin](#page--1-15) [\(2013\)](#page--1-15) and illustrating the advantages of performing covariate adjustment in  $2<sup>K</sup>$  factorial designs. To be specific, we derive the closed-form expressions for the asymptotic precisions of the unadjusted and covariate-adjusted estimators, and thus accurately measure the precision gained by covariate adjustment.

The paper proceeds as follows. Section [2](#page-1-0) reviews randomization-based inference for 2*<sup>K</sup>* factorial designs. Section [3](#page-1-1) introduces the covariate-adjusted estimator for 2*<sup>K</sup>* factorial designs. Section [4](#page--1-16) derives the asymptotic precisions of the unadjusted and covariate-adjusted estimators. Section [5](#page--1-17) concludes and discusses possible future directions.

#### <span id="page-1-0"></span>**2. Randomization inference for 2***<sup>K</sup>* **factorial designs**

In this section, we review the randomization-based inference framework for 2*<sup>K</sup>* factorial designs [\(Dasgupta](#page--1-18) [et al.,](#page--1-18) [2015;](#page--1-18) [Lu,](#page--1-11) [2016\)](#page--1-11). For consistency we adopt the notations in [Lu](#page--1-11) [\(2016\)](#page--1-11).

#### *2.1.* 2 *K factorial designs*

2 *K* factorial designs consist of *K* distinct treatment factors, each of which has two levels coded as −1 and 1. To simplify future notations we let  $J=2^K$ . To define  $2^K$  factorial designs, we rely on a  $J\times J$  orthogonal matrix  $\bm H=(\bm h_0,\ldots,\bm h_{J-1})$ , which is often referred to as the model matrix [\(Wu](#page--1-19) [and](#page--1-19) [Hamada,](#page--1-19) [2009\)](#page--1-19). We construct the model matrix in the following recursive way [\(Espinosa](#page--1-20) [et al.,](#page--1-20) [2016;](#page--1-20) [Lu,](#page--1-11) [2016\)](#page--1-11):

#### 1. Let  $h_0 = 1/2$ ;

- 2. For *<sup>k</sup>* = <sup>1</sup>, . . . , *<sup>K</sup>*, construct *<sup>h</sup><sup>k</sup>* by letting its first 2*<sup>K</sup>*−*<sup>k</sup>* entries be −1, the next 2*<sup>K</sup>*−*<sup>k</sup>* entries be 1, and repeating 2*<sup>k</sup>*−<sup>1</sup> times;
- 3. If  $K \geq 2$ , order all subsets of  $\{1, \ldots, K\}$  with at least two elements, first by cardinality and then lexicography. For

 $k = 1, \ldots, J-1-K$ , let  $\sigma_k$  be the *k*th subset and  $h_{K+k} = \prod_{l \in \sigma_k} h_l$ , where " $\prod$ " stands for entry-wise product.

The *j*th row of the sub-matrix  $\tilde{\bm{H}}=(\bm{h}_1,\ldots,\bm{h}_K)$  is the *j*th treatment combination  $\bm{z}_j$ . To further illustrate the construction of the model matrix, we adopt the example in  $Lu$  [\(2016\)](#page--1-11).

**Example 1.** Let  $K = 2$ . By following the above recursive procedure, we obtain  $h_0 = 1$ ,  $h_1 = (-1, -1, 1, 1)'$ ,  $h_2 = (-1, 1, 1)$  $-1$ , 1<sup>)'</sup>, and **h**<sub>3</sub> =  $(1, -1, -1, 1)$ <sup>'</sup>. Consequently, for 2<sup>2</sup> factorial designs the model matrix is:

$$
H = \begin{pmatrix} h_0 & h_1 & h_2 & h_3 \\ 1 & -1 & -1 & 1 \\ 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 \\ 1 & 1 & 1 & 1 \end{pmatrix}.
$$

The four treatment combinations are  $z_1 = (-1, -1)$ ,  $z_2 = (-1, 1)$ ,  $z_3 = (1, -1)$  and  $z_4 = (1, 1)$ .

#### *2.2. Randomization-based inference*

We allow  $N \geq 2J$  experimental units in the design. To describe the randomization-based inference framework, we follow a three-step procedure.

First, under the Stable Unit Treatment Value Assumption [\(Rubin,](#page--1-21) [1980\)](#page--1-21) that for  $j = 1, \ldots, J$  there is only one version of the treatment combination  $z_j$ , and no interference among the experimental units, let  $Y_i(z_j)$  be the potential outcome of unit *i* under treatment combination  $z_j$ , and  $\bar{Y}(z_j)=N^{-1}\sum_{i=1}^N Y_i(z_j)$  be the average potential outcome across all the experimental units. Let  $Y_i = \{Y_i(z_1), \ldots, Y_i(z_j)\}$  and  $\vec{Y} = \{\vec{Y}(z_1), \ldots, \vec{Y}(z_j)\}$ .

Next, we randomly assign  $n_j \geq 2$  units to treatment combination  $\boldsymbol{z}_j$ . Let

$$
W_i(\mathbf{z}_j) = \begin{cases} 1, & \text{if unit } i \text{ is assigned treatment } \mathbf{z}_j, \\ 0, & \text{otherwise,} \end{cases}
$$

and let  $Y_i^{\text{obs}} = \sum_{j=1}^J W_i(\pmb{z}_j) Y_i(\pmb{z}_j)$  be the observed outcome for unit *i*, and therefore the average observed outcome across all experimental units that are assigned to treatment combination  $z_j$  is  $\bar Y^{\rm obs}(z_j)=n_j^{-1}\sum_{i=1}^N W_i(z_j)Y_i(z_j)$ . Furthermore, we let  $\bar{Y}^{\text{obs}} = {\bar{Y}^{\text{obs}}(z_1), \ldots, \bar{Y}^{\text{obs}}(z_J)}'.$ 

Finally, we define the factorial effects as

$$
\tau(l) = \frac{1}{2^{K-1}} \mathbf{h}'_l \bar{\mathbf{Y}} \quad (l = 1, \ldots, J-1),
$$

and their randomization-based estimators as

$$
\hat{\tau}_{\rm rb}(l) = \frac{1}{2^{K-1}} \mathbf{h}'_l \bar{\mathbf{Y}}^{\rm obs} \quad (l = 1, \dots, J-1). \tag{1}
$$

Its randomness is solely from the treatment assignment *Wi*(*zj*)'s.

#### <span id="page-1-1"></span>**3. Covariate adjustment in 2***<sup>K</sup>* **factorial designs**

The idea behind the randomization-based estimator is estimating the average potential outcome  $\bar{Y}(z_i)$  by its corresponding average observed outcome  $\bar{Y}^{obs}(z_i)$ . However, as shown in [Cochran](#page--1-12) [\(1977\)](#page--1-12) and later mentioned in [Lin](#page--1-15) [\(2013\)](#page--1-15), utilizing the pre-treatment covariates can potentially improve the precision of  $\bar{Y}^{obs}(z_i)$ , and consequently that Download English Version:
