A B S TRACT

The reactions between group 12 metals and the acidic $\mathrm{TaF}_{5}$ were studied in the anhydrous HF (aHF) solvent. We were able to prepare and characterize the first compounds containing metal $\mathrm{M}^{2+}$ cations and undecafluoridodimetallate anions $-\mathrm{M}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}(\mathrm{M}=\mathrm{Cd}, \mathrm{Hg})$ without the additional cations, anions or ligands included in the crystal structure. They both crystallize in $P-1$ space group with cell parameters $a=9.1571(4) \AA, b=9.8750(3) \AA, c=10.9400(7) \AA, \alpha=94.389(4)^{\circ}, \beta=113.124(5)^{\circ}, \gamma=101.142(3)^{\circ}, V=879.81$ (8) $\AA^{3}, \mathrm{Z}=2, \mathrm{~T}=150 \mathrm{~K}\left(\mathrm{Cd}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}\right)$ and $a=9.1381(5) \AA, b=9.8613(6) \AA, c=11.4470(7) \AA, \alpha=114.086(6)^{\circ}$, $\beta=102.290(5)^{\circ}, \gamma=100.398(5)^{\circ}, V=877.84(11) \AA^{3}, Z=2, T=150 \mathrm{~K}\left(\mathrm{Hg}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}\right)$. Metal cations connected through two anions form chains along $b$ axis. $\mathrm{M}\left(\mathrm{HF}_{2}\right)_{2}\left(\mathrm{TaF}_{6}\right)_{2} \cdot \mathrm{nHF}(\mathrm{M}=\mathrm{Cd}, \mathrm{Hg})$ compounds were also prepared in the $\mathrm{MF}_{2} / \mathrm{TaF}_{5}(\mathrm{M}=\mathrm{Cd}, \mathrm{Hg})$ system and their crystal structures were determined.

## 1. Introduction

The undecafluoridodimetalate anions ( $\mathrm{A}_{2} \mathrm{~F}_{11}{ }^{-}$) are less common in superacid chemistry than the monomeric $\mathrm{AF}_{6}{ }^{-}$species. They are obtained when excess parent Lewis acid $\mathrm{AF}_{5}$ coordinates to fluoride ion in the solution to form $\mathrm{A}_{2} \mathrm{~F}_{11}{ }^{-}$anion. Only the strongest Lewis acids $\mathrm{AF}_{5}(\mathrm{~A}=\mathrm{As}, \mathrm{Sb}, \mathrm{Ru}, \mathrm{Ir}, \mathrm{Bi}, \mathrm{Nb}, \mathrm{Ta}, \mathrm{Pt})$ tend to form such dimeric anions, but only systems containing $\mathrm{Sb}_{2} \mathrm{~F}_{11}{ }^{-}$were studied more extensively. In most of those systems counter-cation is in +1 oxidation state. There are different reports on the preparation of pure $\mathrm{M}\left(\mathrm{AF}_{6}\right)_{2}$ compound prepared by the reaction between corresponding metal difluorides and $\mathrm{AF}_{5}(\mathrm{~A}=\mathrm{As}, \mathrm{Sb}$, etc.) fluoride-ion acceptors [1,2]. However crystallization from different solvents like $\mathrm{SO}_{2}, \mathrm{CH}_{3} \mathrm{CN}$ [3-5] and even anhydrous hydrogen fluoride (aHF), that is considered a weak ligand, mostly yields products with solvent coordinated to the metal center. UV-vis spectra of solutions containing Lewis acids ( $\mathrm{AsF}_{5}, \mathrm{BF}_{3}$, etc.) and $\mathrm{MF}_{2}$ in aHF show that metal centers are surrounded by HF molecules [6], that can be removed or partially removed during the isolation. $\mathrm{A}_{2} \mathrm{~F}_{11}{ }^{-}$anions are larger than all other species in $\mathrm{MF}_{2} / \mathrm{AF}_{5} / \mathrm{aHF}$ system mentioned before therefore similar could be expected for $\mathrm{M}\left(\mathrm{A}_{2} \mathrm{~F}_{11}\right)_{2}$ compounds with metal $2+$ cations. As expected all the reported compounds contain either other cations and anions $\left(\mathrm{H}_{3} \mathrm{O}\right) \mathrm{Cd}\left(\mathrm{SbF}_{6}\right)\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)_{2},\left(\mathrm{H}_{3} \mathrm{O}\right)_{2} \mathrm{Cd}\left(\mathrm{SbF}_{6}\right)_{3}\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)[7], \mathrm{AuXe}_{2} \mathrm{~F}\left(\mathrm{SbF}_{6}\right)$ $\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)$ [8] or just neutral ligands $\mathrm{AuXe}_{2}\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)_{2}$ [8], AuX$\mathrm{e}_{4}\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)_{2}$ [9], $\mathrm{M}(\mathrm{CO})_{\mathrm{n}}\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)_{2}(\mathrm{M}=\mathrm{Hg}, \mathrm{Pd}, \mathrm{Pt}, \mathrm{Fe}, \mathrm{Ru}, \mathrm{Os} ; \mathrm{n}=2-$

[^0]6) [10]. On the other hand no $\mathrm{M}\left(\mathrm{A}_{2} \mathrm{~F}_{11}\right)_{2}$ compound without additional ligand and with metal $\mathrm{M}^{2+}$ cations have been reported so far.

Our intention was to prepare and study the geometry of M $\left(\mathrm{A}_{2} \mathrm{~F}_{11}\right)_{2}$ compounds without the influence of additional coordinated ligands or other cations that could influence its formation or geometry. Group 12 elements were selected because related products were observed for cadmium - $\left(\mathrm{H}_{3} \mathrm{O}\right) \mathrm{Cd}\left(\mathrm{SbF}_{6}\right)\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)_{2}$ and $\left(\mathrm{H}_{3} \mathrm{O}\right)_{2} \mathrm{Cd}\left(\mathrm{SbF}_{6}\right)_{3}\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)$ [7], while $\mathrm{Hg}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$ in $\mathrm{SO}_{2}$ solution was mentioned in the literature [11] without direct proof of its existence and composition. From all the suitable $\mathrm{AF}_{5}$ Lewis acids $\mathrm{TaF}_{5}$ was chosen as an acidic building block instead of widely used $\mathrm{SbF}_{5}$ because it is not volatile at room temperature [12]. Consequently formed oligomers should have higher stability during crystallization or isolation. The only drawback of the $\mathrm{TaF}_{5}$ is its lower solubility in aHF, which could influence its reactivity and formation of oligomeric species [13]. $\mathrm{Ta}_{2} \mathrm{~F}_{11}{ }^{-}$anion can be rarely found in the literature and in most cases it is not structurally characterized. Examples of characterized compounds containing $\mathrm{Ta}_{2} \mathrm{~F}_{11}{ }^{-}$anion that can be found in the literature are: $\mathrm{O}_{2} \mathrm{Ta}_{2} \mathrm{~F}_{11}, \mathrm{CsTa}_{2} \mathrm{~F}_{11}, \mathrm{XeFTa}_{2} \mathrm{~F}_{11}$ [14], [2,4-(OMe) $\left.)_{2} \mathrm{C}_{6} \mathrm{H}_{5}\right]\left[\mathrm{Ta}_{2} \mathrm{~F}_{11}\right]$ [15], TBATa $_{2} \mathrm{~F}_{11}$ [16], $\mathrm{Hg}_{4}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$ [11].

## 2. Results and discussion

Synthesis in stoichiometric ratio between the $\mathrm{MF}_{2}(\mathrm{M}=\mathrm{Cd}, \mathrm{Hg})$ and $\mathrm{TaF}_{5}$ (1:4) in aHF led to formation of $\mathrm{Cd}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$ and Hg $\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$. Products are structurally related and both crystallize in triclinic $P-1$ space group.

Metal centres in crystal structures are surrounded by eight fluorine atoms from four $\mathrm{Ta}_{2} \mathrm{~F}_{11}$ units in deformed square antiprism arrangement. (Figs. 1 and 2)

Both $\mathrm{Ta}_{2} \mathrm{~F}_{11}$ groups from asymmetric unit act as bidentate bridging ligands connecting two cadmium or mercury metal centers into chains along $b$ axis (Figs. 3 and 4).
$\mathrm{Cd}-\mathrm{F}$ distances in the crystal structure of $\mathrm{Cd}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$ are in range from $2.251(4)$ to $2.410(4) \AA$ (Fig. 1) which is similar to distances in $\mathrm{CdF}_{2}$ ( $2.333 \AA$ ) [17]. Both crystallographically different $\mathrm{Ta}_{2} \mathrm{~F}_{11}{ }^{-}$anions in the crystal structure are coordinated to two different cadmium atoms as bidentate bridging ligand (Fig. 5).

All Ta- $\mathrm{F}(\mathrm{Cd})$ bond distances are elongated and are in range from $1.918(4)$ to $1.942(4) \AA$. Polarization of the anion reduces nonbridging Ta-F distances which are in range from 1.821(4) to 1.851 (4) with the Ta-F distances opposite to $\mathrm{Ta}-\mathrm{F}(\mathrm{Ta})$ bond being the shortest. Bridging Ta-F(Ta) distances are from 2.056(4) to 2.077(4) $\AA$. Cd to Cd distances in chain are 4.901(1) and 4.976(1) $\AA$, which is well over the sum of Van der Waals radii, negating any possibility of direct metal-metal bonding [18].
$\mathrm{Hg}-\mathrm{F}$ distances in the crystal structure of $\mathrm{Hg}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$ are in range from 2.329 (6) to $2.428(6)$ A which is comparable to distances in $\mathrm{HgF}_{2} 2.40 \AA$ [19]. $\mathrm{Ta}-\mathrm{F}(\mathrm{Hg})$ distances are elongated and are in range from 1.926(7) to 1.948(6) Å. Non-bridging Ta-F distances are reduced similarly than in the crystal structure of $\mathrm{Cd}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$. Bridging Ta-F(Ta) distances are from 2.059(6) to 2.069(6) Å. Distances between neighboring Hg atoms in the same chain are 4.902(1) and 4.961(1) $\AA$, which is again longer than the sum of Van der Waals radii [18].

The $\mathrm{A}_{2} \mathrm{~F}_{11}{ }^{-}$anions are considered weak ligands, and can be easily removed from coordination sphere of a metal cation in the presence of stronger ligands like CO [10]. On the other hand they tend to bend and orient themselves in such a way that they maximize the number of interactions with the cations through either hydrogen bonds $[20,21$ ] or act as a chelating ligands [7$9,22,23]$. As a consequence of those effects, $\mathrm{A}_{2} \mathrm{~F}_{11}{ }^{-}$anions are heavily distorted in practically all the crystal structures determined so far when measured by A-F-A bridge angles together with the torsion angle between two planar $\mathrm{SbF}_{4 \mathrm{eq}}$ groups from eclipsed

Fig. 1. Coordination sphere of Cd in the crystal structure of $\mathrm{Cd}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$. Thermal ellipsoids are drawn at the $50 \%$ probability. Symmetry codes: (i) $2-x, 1-y, 2-z$; (ii) $2-x, 2-y, 2-z$.

Fig. 2. Coordination sphere of Hg in the crystal structure of $\mathrm{Hg}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$. Thermal ellipsoids are drawn at the $50 \%$ probability. Symmetry codes: (i) $-x, 1-y, 1-z$; (ii) $-x, 2-y, 1-z$.
to staggered conformation [24]. Gas phase calculations show that $\mathrm{A}_{2} \mathrm{~F}_{11}{ }^{-}$anions should exist in $D_{4 h}$ symmetry [25], which is supported by recent crystal structure of the $\left[2,4-(\mathrm{OMe})_{2} \mathrm{C}_{6} \mathrm{H}_{5}\right]$ $\left[A_{2} F_{11}\right](A=N b, T a)$. The $A_{2} \mathrm{~F}_{11}{ }^{-}$anion is completely linear in the described compound and is sandwiched between two arenium rings. DFT calculations for that system with $\mathrm{Nb}_{2} \mathrm{~F}_{11}{ }^{-}$anion showed, that considering the interactions between a single anion and two adjacent arenium cations, a pile arrangement is theoretically favored, thus forcing the linearity of the $\mathrm{Nb}-\mathrm{F}-\mathrm{Nb}$ bridge. Conversely, the calculated structure related to one ion-pair in the gas phase shows bent $\mathrm{Nb}-\mathrm{F}-\mathrm{Nb}$ angle (159.5) ${ }^{\circ}$ [15].

Bidentate coordination to two different metal atoms forces $\mathrm{Ta}_{2} \mathrm{~F}_{11}{ }^{-}$anions to adopt even more distorted shape, which is shown in bridging Ta-F-Ta angles being 149.8(2) ${ }^{\circ}$ and 149.9(2) ${ }^{\circ}$ (dihedral angles $\left.27.5(1)^{\circ}, 23.4(1)^{\circ}\right)$ in the crystal structure of $\mathrm{Cd}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$, while the mercury analogue is slightly less distorted with Ta-F-Ta angles of $151.7(3)^{\circ}$ and $154.1(4)^{\circ}$ (dihedral angles $16.2(2)^{\circ}, 23.9$ (2) ${ }^{\circ}$ ) (Fig. 6), probably as a consequence of slightly larger crystal radius of $\mathrm{Hg}^{2+}\left(1.28, \mathrm{Hg}^{2+} ; 1.24, \mathrm{Cd}^{2+}\right)[26]$. Ta-F-Ta angle in related mercury compound $-\mathrm{Hg}_{4}\left(\mathrm{Ta}_{2} \mathrm{~F}_{11}\right)_{2}$ is $153(1)^{\circ}$ [11], which is comparable to the ones obtained in the current study.

Such effects can also be seen in $\left(\mathrm{H}_{3} \mathrm{O}\right) \mathrm{Cd}\left(\mathrm{SbF}_{6}\right)\left(\mathrm{Sb}_{2} \mathrm{~F}_{11}\right)_{2}$ where one $\mathrm{Sb}_{2} \mathrm{~F}_{11}{ }^{-}$anion is tridentately coordinated to single cadmium cation having $\mathrm{Sb}-\mathrm{F}-\mathrm{Sb}$ angle as low as 143.1(3) ${ }^{\circ}$, while the other $\mathrm{Sb}_{2} \mathrm{~F}_{11}{ }^{-}$anion with bidentate coordination has $147.9(2)^{\circ}$ angle [7]. Type of coordination influences torsion angle to a degree that cation and especially type of bonding to it dictates anion conformation in a crystal structure.

Reactions of both $\mathrm{HgF}_{2}$ and $\mathrm{CdF}_{2}$ with $\mathrm{TaF}_{5}$ in 1:2 molar ratio resulted in $\mathrm{M}\left(\mathrm{TaF}_{6}\right)_{2}$ type of compound as expected, but crystallization of the product from solvent aHF ended up with $\mathrm{Cd}(\mathrm{HF})_{2}\left(\mathrm{TaF}_{6}\right)_{2} \cdot \mathrm{nHF}$ and $\mathrm{Hg}\left(\mathrm{HF}_{2}\left(\mathrm{TaF}_{6}\right)_{2} \cdot \mathrm{nHF} . \mathrm{Cd}\left(\mathrm{HF}_{2}\right)_{2}\left(\mathrm{TaF}_{6}\right)_{2} \cdot \mathrm{nHF}\right.$ crystallizes in $P-1$ space group. Central cadmium atom has preferred coordination number 8 and is surrounded by 6 fluorine atoms from $\mathrm{TaF}_{6}$ units and 2 fluorine atoms from coordinated HF molecules (Fig. 7). Basic building blocks consist of eight membered rings containing 2 cadmium, 2 tantalum and 4 fluorine atoms that are further connected into layers running along $c$ axis. $\mathrm{Cd}-\mathrm{F}(\mathrm{Ta})$ distances are from 2.218(4) to 2.301(4) Å, while Cd-F(HF) are 2.419 (5) and 2.674(7) $\AA . \operatorname{HF}(3)$ molecule is located outside the metal coordination sphere between two layers and is fixed in the crystal
