Abstract

Connectivity and diagnosability are two important parameters for the fault tolerant of an interconnection network G . In 1996, Fàbrega and Fiol proposed the g -good-neighbor connectivity of G . In this paper, we show that $1 \leq \kappa^g(G) \leq n - 2g - 2$ for $0 \leq g \leq \{\Delta(G), \lfloor \frac{n-3}{2} \rfloor\}$, and graphs with $\kappa^g(G) = 1, 2$ and trees with $\kappa^g(T_n) = n - t$ for $4 \leq t \leq \frac{n+2}{2}$ are characterized, respectively. In the end, we get the three extremal results for the g -good-neighbor connectivity.

Keywords: Connectivity, g -good-neighbor connectivity, extremal problem.

AMS subject classification 2010: 05C40; 05C05; 05C76.

1 Introduction

With the rapid development of VLSI technology, a multiprocessor system may contain hundreds or even thousands of nodes, and some of them may be faulty when the system is implemented. As the number of processors in a system increases, the possibility that its processors may be come faulty also increases. Because designing such systems without defects is nearly impossible, reliability and fault tolerance are two of the most critical concerns of multiprocessor systems [38].
