Coprecipitation

Uptake

Rare earth

## ABSTRACT

A Cu–Al layered double hydroxide intercalated with ethylenediaminetetraacetate (edta•Cu–Al LDH) was prepared by the dropwise addition of a Cu–Al nitrate solution to an edta solution at constant pH values of 8.0, 9.0, and 10.0. The edta•Cu–Al LDH had Hedta<sup>3−</sup> in the interlayer. Furthermore, the preparation at pH 8.0 resulted in the intercalation of Cu(edta)<sup>2−</sup>. The edta•Cu–Al LDH was found to take up rare earth ions from aqueous solution. The uptake of Sc<sup>3+</sup> and Y<sup>3+</sup> by edta•Cu–Al LDH was attributed to both the chelating functions of the edta ion in the interlayer and the chemical properties of Cu–Al LDH itself. The uptake of La<sup>3+</sup> by edta•Cu–Al LDH was primarily caused by the chelating function of edta ions in the interlayer. The edta ions in the edta•Cu–Al LDH interlayer formed chelate complexes in the order Sc<sup>3+</sup> > Y<sup>3+</sup> > La<sup>3+</sup> due to their relative stabilities, Sc(edta)<sup>−</sup> > Y(edta)<sup>−</sup> > La(edta)<sup>−</sup>. Thus, edta ions retain their chelating function even when intercalated in a Cu–Al LDH interlayer.

## 1. Introduction

Layered double hydroxides (LDHs) have anion-exchange capabilities and are represented by the chemical formula  $[M_1^{2+}_x M_2^{3+}_{3-x}(\text{OH})_2](\text{A}^{n-})_x/n \cdot m\text{H}_2\text{O}$ , where  $M^{2+}$  can be Mg<sup>2+</sup>, Ni<sup>2+</sup>, Zn<sup>2+</sup>, etc.;  $M^{3+}$  can be Al<sup>3+</sup>, Fe<sup>3+</sup>, etc.;  $\text{A}^{n-}$  can be CO<sub>3</sub><sup>2−</sup>, Cl<sup>−</sup>, etc.; and  $x$  is the  $M^{3+}/(M^{2+} + M^{3+})$  molar ratio ( $0.20 \leq x \leq 0.33$ ) [1]. LDHs have been examined for the preservation of aqueous environments, i.e., the removal of hexavalent chromium, selenite, arsenate, Acid Blue 9, humic acid, fulvic acid, anionic surfactants, phenol, 2,4-dichlorophenoxyacetic acid, nitrophenol pesticide, and nitrate [2–10]. Organic-modified LDH can take up cationic metals from an aqueous solution. For example, Mg–Al LDH, Zn–Al LDH, and Mg–Fe LDH intercalated with ethylenediaminetetraacetate (edta) can take up heavy metal ions, such as Cu<sup>2+</sup>, Cd<sup>2+</sup>, Pb<sup>2+</sup>, Ni<sup>2+</sup>, Co<sup>2+</sup>, Cs<sup>+</sup>, Sr<sup>2+</sup>, and Y<sup>3+</sup>, in the cationic form from aqueous solution [11–16]. The uptake of heavy metal ions such as Cu<sup>2+</sup>, Cd<sup>2+</sup>, Pb<sup>2+</sup>, and Hg<sup>2+</sup> by Mg–Al LDH and Zn–Al LDH intercalated with other chelating agents, such as mercapto-carboxylic, diethylenetriaminepentaacetate, and meso-2,3-dimercaptosuccinate, has also been investigated [17–19]. Mg–Al

LDHs intercalated with citrate, malate, and tartrate can also take up heavy metal ions such as Cu<sup>2+</sup> and Cd<sup>2+</sup> from an aqueous solution [20–22].

Recently, we found that Cu–Al LDH intercalated with edta (edta•Cu–Al LDH) could be prepared by suspending Cu–Al oxide, obtained by the calcination of CO<sub>3</sub><sup>2−</sup>-intercalated Cu–Al LDH, in an edta solution [23]. The edta•Cu–Al LDH was found to take up rare earth ions such as Sc<sup>3+</sup> and La<sup>3+</sup> in aqueous solution at pH 6–6.5. This behavior is mainly attributed to the chelating function of edta ions in the interlayer. The edta•Cu–Al LDH had an edta/Al molar ratio of 0.12, one-third of the expected value, because of the intercalations of both the OH<sup>−</sup> released from Cu–Al oxide and the CO<sub>3</sub><sup>2−</sup> remaining in Cu–Al oxide as additional interlayer anions. This low edta content required a relatively large amount of edta•Cu–Al LDH to take up a given amount of rare earth ions from aqueous solution. To achieve the effective uptake of rare earth ions using a small amount of edta•Cu–Al LDH, the edta•Cu–Al LDH must have a high content of edta ions in its interlayer. To this end, this study examined the preparation of edta•Cu–Al LDH by coprecipitation and the effect of preparation pH. Low pH values prevent the intercalation of OH<sup>−</sup> in solution. The prepared edta•Cu–Al LDH has been hereafter examined for the uptake of Sc<sup>3+</sup>, Y<sup>3+</sup>, and La<sup>3+</sup> in aqueous solution.

## 2. Experimental details

All the reagents were of chemical reagent grade and were used without further purification.

### 2.1. Preparation

The  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH was prepared by the dropwise addition of a  $\text{Cu}-\text{Al}$  nitrate solution to an  $\text{edta}$  solution at constant pH values of 8.0, 9.0, and 10.0. In this pH range,  $\text{Hedta}^{3-}$  is a stable anionic species of  $\text{edta}$  [24]. The theoretical formula is therefore described as  $\text{Cu}_{0.75}\text{Al}_{0.25}(\text{OH})_2(\text{Hedta})_{0.0833}$ . The coprecipitation reaction is expressed by Eq. (1), in which the stoichiometric coefficient for  $\text{Hedta}^{3-}$  was calculated using the neutralization of the excess positive charge in the  $\text{Al}$ -bearing brucite-like octahedral layers by the replacement of  $\text{Cu}$  with  $\text{Al}$  at a  $\text{Cu}/\text{Al}$  molar ratio of 3.0:

A  $\text{Cu}-\text{Al}$  solution ( $0.375 \text{ mol/L Cu}(\text{NO}_3)_2 + 0.125 \text{ mol/L Al}(\text{NO}_3)_3$ ) with a  $\text{Cu}/\text{Al}$  molar ratio of 3.0 was prepared by dissolving  $\text{Cu}(\text{NO}_3)_2\cdot 3\text{H}_2\text{O}$  (93.75 mmol) and  $\text{Al}(\text{NO}_3)_3\cdot 9\text{H}_2\text{O}$  (31.25 mmol) in 250 mL of deionized water. The  $\text{edta}$  solution was prepared by dissolving twice the stoichiometric amounts of  $\text{edta}-2\text{Na}$ ,  $\text{C}_{10}\text{H}_{14}\text{N}_2\text{Na}_2\text{O}_8$ , defined by Eq. (1) in 250 mL of deionized water. The  $\text{Cu}-\text{Al}$  solution was added dropwise to the  $\text{edta}$  solution at a rate of 10 mL/min at  $30^\circ\text{C}$  under mild agitation. The solution was adjusted to pH 8.0–10.0 by adding 1.0 mol/L  $\text{NaOH}$  solution until a pH meter indicated that the desired pH had been reached. After the addition of the  $\text{Cu}-\text{Al}$  solution, the resultant suspensions were kept at  $30^\circ\text{C}$  for 1 h at a constant pH of 8.0–10.0. The  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH particles were recovered by filtering the resultant suspension, repeated washing with deionized water, and drying under reduced pressure (133 Pa) for 40 h. Nitrogen gas was bubbled into the solution throughout the operation to minimize the effects of dissolved  $\text{CO}_2$ .

### 2.2. Uptake of rare earth ions from aqueous solution

The  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH was added to 500 mL of 1.0 mmol/L  $\text{ScCl}_3$ ,  $\text{YCl}_3$ , or  $\text{LaCl}_3$  solution, and the resultant suspension was kept standing at  $30^\circ\text{C}$  for 120 min with stirring of 300 rpm.  $\text{N}_2$  was bubbled into the solution throughout the operation. Samples of the suspension were extracted at different time intervals and immediately filtered through a  $0.45\text{-}\mu\text{m}$  membrane filter after measuring the pH. The filtrates were submitted for analyses of the target metal ions. The molar ratios of  $\text{edta}$  in  $\text{Cu}-\text{Al}$  LDH to  $\text{Sc}^{3+}$ ,  $\text{Y}^{3+}$ , and  $\text{La}^{3+}$  in the chloride solution were set at 1, 2, 3, and 4.  $\text{NO}_3\bullet\text{Cu}-\text{Al}$  LDH was also used in this experiment as a reference material to demonstrate the effect of the interlayer anion.

### 2.3. Characterization methods

The  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH;  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH loaded with  $\text{Sc}^{3+}$ ,  $\text{Y}^{3+}$ , and  $\text{La}^{3+}$ ;  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH; and  $\text{NO}_3\bullet\text{Cu}-\text{Al}$  LDH were analyzed by X-ray diffraction (XRD) using  $\text{CuK}\alpha$  radiation. In this case, the  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH was used as a reference to confirm that the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH was indeed a layered double hydroxide. Furthermore, the materials were dissolved in 1 mol/L  $\text{HNO}_3$  and analyzed for  $\text{Cu}^{2+}$  and  $\text{Al}^{3+}$  by inductively coupled plasma-atomic emission spectrometry (ICP-AES). The materials were dissolved in 1 mol/L  $\text{HCl}$  and analyzed for  $\text{edta}$  based on the total organic carbon (TOC).

For the adsorption experiments, the residual concentrations of  $\text{Sc}^{3+}$ ,  $\text{Y}^{3+}$ , and  $\text{La}^{3+}$  in the filtrates were determined by ICP-AES. The

concentrations of  $\text{Cu}^{2+}$  dissolved from  $\text{Cu}-\text{Al}$  LDHs into the filtrates were also determined by ICP-AES.

### 2.4. Theoretical calculations

The molecular geometry of isolated  $\text{H}_4\text{edta}$  in the ground state was calculated by an *ab initio* Hartree–Fock method utilizing an STO-3G basis set in Gaussian 03 [25].

## 3. Results and discussion

### 3.1. Preparation

Table 1 shows the chemical compositions of the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs prepared at various pH values. The  $\text{Cu}/\text{Al}$  molar ratios were approximately 3, which was the value expected from Eq. (1), and within the range (2.0–4.0) in which  $\text{Cu}-\text{Al}$  LDH was formed. The  $\text{edta}/\text{Al}$  molar ratios were approximately 0.3–0.4. The theoretical  $\text{edta}/\text{Al}$  molar ratio based on charge balance with the  $\text{Cu}-\text{Al}$  LDH is 0.33, as shown in Eq. (1). The  $\text{edta}/\text{Al}$  molar ratios for the samples were close to the theoretical value, suggesting that  $\text{Hedta}^{3-}$  was intercalated in the  $\text{Cu}-\text{Al}$  LDH interlayer.

Fig. 1 shows the XRD patterns for the  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH,  $\text{NO}_3\bullet\text{Cu}-\text{Al}$  LDH, and  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs prepared at pH 8.0–10.0. The XRD peaks for  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH (Fig. 1a) were ascribed to copper aluminum carbonate hydroxide hydrate (JCPDS card 37-630) formulated as  $\text{Cu}_6\text{Al}_2(\text{OH})_{16}\text{CO}_3\cdot 4\text{H}_2\text{O}$  with a layered double hydroxide structure. For  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH, the observed basal spacing  $d_{003}$  was 7.6 Å, with an LDH host layer thickness of approximately 4.8 Å and an interlayer spacing of 2.8 Å. The  $d_{006}$  value, 3.8 Å, was half of the  $d_{003}$  value, confirming that the  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH was a layered material. The XRD peaks for  $\text{NO}_3\bullet\text{Cu}-\text{Al}$  LDH (Fig. 1b) were broader than those for  $\text{CO}_3\bullet\text{Cu}-\text{Al}$  LDH (Fig. 1a) but suggest the structure of a layered double hydroxide [23]. The intercalation of  $\text{NO}_3^-$ , which was larger than that of  $\text{CO}_3^{2-}$ , in the interlayer of  $\text{Cu}-\text{Al}$  LDH resulted in an increase in the basal spacing from 7.6 Å to 8.6 Å. The XRD peaks for  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs (Fig. 1c–e) were similar to those for  $\text{NO}_3\bullet\text{Cu}-\text{Al}$  LDH (Fig. 1b), indicating that the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs have a layered double hydroxide structure. Although the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs were prepared from nitrate solution, the basal spacing increased from 8.6 Å to approximately 15 Å, suggesting the intercalation of  $\text{Hedta}^{3-}$ , which was larger than  $\text{NO}_3^-$ , in the interlayer of  $\text{Cu}-\text{Al}$  LDH. The  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs had well-ordered spacing corresponding to reflections of (001). For example, the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDH prepared at pH 8.0 (Fig. 1c) had diffraction peaks at  $2\theta$  values of  $6^\circ$ ,  $12^\circ$ ,  $19^\circ$ , and  $25^\circ$ , corresponding to the spacings  $d = 15.2$ , 7.1, 4.8, and 3.6 Å, respectively, which is likely derived from the (001) reflections. For the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs prepared at pH 9.0 and 10.0 (Fig. 1d and e), the XRD peaks at  $2\theta$  values of  $6^\circ$ , corresponding to the spacing  $d = 15$  Å, decreased in intensity. This change is attributed to the expansion of the amorphous state caused by the intercalation of  $\text{OH}^-$  in the interlayer of  $\text{Cu}-\text{Al}$  LDH. Higher preparation pH values most likely resulted in the intercalation of  $\text{OH}^-$ , which was supported by the decrease in the  $\text{edta}/\text{Al}$  molar ratio with increasing pH, as shown in Table 1.

The XRD patterns shown in Fig. 1c–e show that the  $\text{edta}\bullet\text{Cu}-\text{Al}$  LDHs have basal spacings of 15.2, 15.1, and 14.7 Å with interlayer
