ABSTRACT

Total and partial densities of states of constituent atoms of two tetragonal phases of Tl_3PbCl_5 (space groups P4_12_12 and P4_1) have been calculated using the full potential linearized augmented plane wave (FP-LAPW) method and Korringa–Kohn–Rostoker method within coherent potential approximation (KKR-CPA). The results obtained reveal the similarity of occupations of the valence band and the conduction band in the both tetragonal phases of Tl_3PbCl_5 . The FP-LAPW and KKR-CPA data indicate that the valence band of Tl_3PbCl_5 is dominated by contributions of the Cl 3p-like states, which contribute mainly to the top and the central portion of the valence band with also significant contributions throughout the whole valence-band region. Further, the bottom of the valence band of Tl_3PbCl_5 is composed mainly of the Tl 6s-like states, while the bottom of the conduction band is dominated by contributions of the empty Pb 6p-like states. The KKR-CPA results allow to assume that the width of the valence band increases somewhat while band gap, E_g , decreases when changing the crystal structure from P4_12_12 to P4_1 . The X-ray photoelectron core-level and valence-band spectra for pristine and Ar^+ -ion-irradiated surfaces of a Tl_3PbCl_5 monocrystal grown by the Bridgman–Stockbarger method have been measured.

1. Introduction

In recent years a lot of attention has been paid to technologies of development and investigation of non-linear optical crystals for middle infrared (3–12 μm) laser sources for applications in free space communications, remote sensing, medical diagnostics, etc. [1]. Such applications require high output power/energy, stable and compact devices as well as no moisture-sensitive materials at room-temperature operations [1]. In the past, chalcogenides and rare-earth chlorides, partly $\text{Dy}^{3+}:\text{CaGa}_2\text{S}_4$ lasing at 2.43 and 4.31 μm [2] and $\text{Pr}^{3+}:\text{LaCl}_3$ lasing at 5.2 and 7.2 μm [3,4], were considered as promising laser crystalline hosts for middle infrared (mid-IR) applications. Nevertheless, these crystals are found to be strongly hygroscopic; this disadvantage prevents their development as efficient laser sources. The requirement of non-hygroscopic materials has generated a number of investigations regarding growth of several no moisture-sensitive complex halide-bearing crystals to find alternative solutions. Among promising halides for mid-IR laser applications, KPb_2Cl_5 ,

KPb_2Br_5 , RbPb_2Br_5 , CsCdBr_3 , Tl_4HgI_6 , Tl_4PbI_6 , Tl_3PbBr_5 , Tl_3PbI_5 , Tl_3PbCl_5 , etc. have been reported [1,4–11]. Tl_3PbCl_5 halide is of particular interest. Tl_3PbCl_5 crystallizes [12] in the $\text{TlCl}_3\text{–PbCl}_2$ system, which melts congruently at 395 °C [5]. Tl_3PbCl_5 single crystals are transparent in the range of 0.5–20 μm , non-hygroscopic and uniaxial [11]. An elliptically deformed circular cross-section is characteristic of Tl_3PbCl_5 single crystals that can be easily grown from the liquid state by the Bridgman–Stockbarger method [11].

Two phases, both possessing a tetragonal symmetry (Fig. 1), have been reported for Tl_3PbCl_5 . Keller [13] was first to solve a crystalline symmetry and to determine unit cell parameters of Tl_3PbCl_5 on single crystals grown from liquid state; however, his space group for this compound (P4_1) was not confirmed by other authors. Partly, Skarstad et al. [14] have reported that grown by the Bridgman method Tl_3PbCl_5 single crystals crystallize in a tetragonal symmetry with four formula units per unit cell, but in the non-centrosymmetric space group P4_12_12 (no. 92). Owing to this space group, both Tl^+ and Pb^{2+} cations occupy the equivalent 8b sites (Table 1). Therefore, the formula for this compound can be appropriately written as $(\text{Tl}_{0.75}\text{Pb}_{0.25})_4\text{Cl}_5$ [14]. The findings by Skarstad et al. [14] have been confirmed comparatively recently by detailed X-ray single-crystal diffraction

measurements [11] on Tl_3PbCl_5 grown by the Bridgman–Stockbarger method (see Table 1).

In 1983, based on differential thermal analysis, Keller [5] reported for Tl_3PbCl_5 the existence of a first-order phase transition

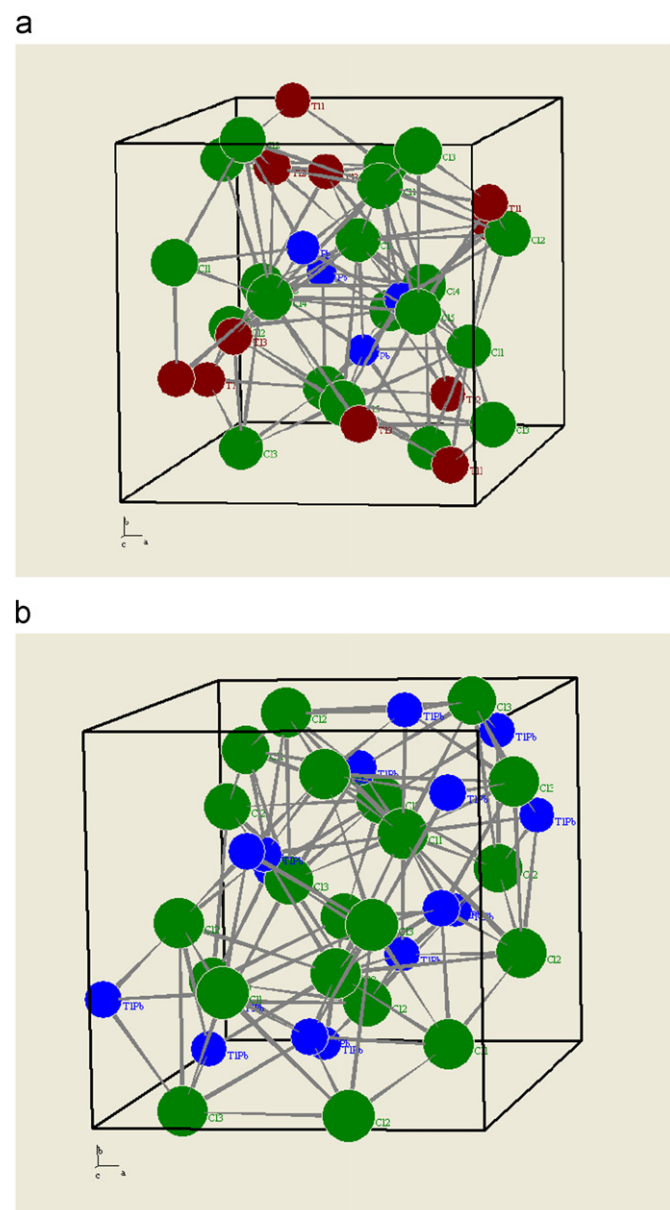

Fig. 1. Crystal structure of (a) HT- Tl_3PbCl_5 (space group $P4_1$; no. 76; Cl—large green balls, Tl—middle brown balls and Pb—small blue balls) and (b) RT- Tl_3PbCl_5 (space group $P4_12_12$; no. 92; Cl—large green balls, Tl and Pb—small blue balls) phases. occurring at $155 \text{ }^\circ\text{C}$. The above first-order transition was suggested to be due to the ordering of Tl^+ and Pb^{2+} cations leaving unchanged positions of Cl^- anions [5]. Lattice parameters and atomic positions of this ordered Tl_3PbCl_5 phase crystallizing in a tetragonal symmetry with four formula units per unit cell (space group $P4_1$; no. 76) are listed in Table 2. Ferrier et al. [11] confirmed a phase transition in Tl_3PbCl_5 , however occurring at $171 \text{ }^\circ\text{C}$ (instead of $155 \text{ }^\circ\text{C}$ reported by Keller [5]). Nevertheless, Ferrier et al. [11] were unable to interpret this transition occurring in Tl_3PbCl_5 .

To the best of our knowledge, the electronic structure of Tl_3PbCl_5 was not studied both from a theoretical and an experimental point of view. Therefore, in the present paper we aim at a comprehensive study of the energy distribution of electronic states of different symmetries of constituent atoms of Tl_3PbCl_5 . With this purpose, we employ possibilities of the full potential linearized augmented plane wave (FP-LAPW) method as incorporated in the WIEN97 code [15] in order to study total density of states (DOS) and partial densities of states of the ordered Tl_3PbCl_5 phase crystallizing in the space group $P4_1$ (no. 76). For clarity, we shall refer to this phase as high-temperature (HT) Tl_3PbCl_5 . Additionally, the electronic structure of the Tl_3PbCl_5 phase with statistical occupation of the equivalent 8b sites by Tl^+ and Pb^{2+} cations (space group $P4_12_12$; no. 92; we shall refer to this phase as room-temperature (RT) Tl_3PbCl_5) was calculated employing the possibility of the Korringa–Kohn–Rostoker method within coherent potential approximation (KKR-CPA) [16]. The latter method was used also to calculate the electronic structure of the HT- Tl_3PbCl_5 phase. Further, we have used possibilities of the X-ray photoelectron spectroscopy (XPS) method to study the XPS valence-band spectrum as well as to measure the binding energies (BEs) of core-level electrons of constituent atoms of RT- Tl_3PbCl_5 . The influence of 1.5 keV Ar^+ bombardment on the XPS valence-band and core-level spectra of RT- Tl_3PbCl_5 surface is also within the scope of the present study. For experimental measurements, we have used a Tl_3PbCl_5 crystal grown by the Bridgman–Stockbarger method.
