### Abstract

The investigation of bulk  $\text{Cr}_2\text{AlC}$  ceramic fabricated by Spark Plasma Sintering (SPS) from coarse powders (CAC10) and fine powders (NCAC10) in the temperature range of 1100–1400 °C was carried out. The XRD results indicate that  $\text{Cr}_2\text{AlC}$ , as major phase, always appears with minor and trace amount of  $\text{Cr}_7\text{C}_3$  and  $\text{Cr}_2\text{Al}$  respectively in both NCAC10 and CAC10 samples and the amounts of later two phases decrease with increase in temperature. However, the  $\text{Cr}_2\text{AlC}$  phase content in NCAC10 is higher than that of CAC10 sintered at the same temperature. The micrographs of back-scattered SEM show that grains with smaller size and pores with fewer amounts appear in SPSed NCAC10 in comparison to that of CAC10. As consequence, the higher hardness (5.6 GPa) of NCAC10 than that (3.9 GPa) of CAC10 was obtained. The patterns of XRD, microstructure and hardness of samples HPed at 1400 °C for the same composition were also presented for comparison.

### 1. Introduction

The ternary carbides, such as  $\text{Ti}_3\text{SiC}_2$  [1,2],  $\text{Ti}_3\text{AlC}_2$  [3] and  $\text{Ti}_2\text{AlC}$  [4], have aroused researchers' more and more interest because of their excellent mechanical, thermal, electrical and chemical properties, in which the carbides belong to  $\text{M}_{n+1}\text{AX}_n$  system (where  $n=1, 2, 3$ , M is an early transition metal, A is an IIIA or IVA element, and X is C or N, abbreviated as MAX) and the same hexagonal group of  $\text{P6}_3/\text{mmc}$ .

As a member of MAX system, the lattice parameters of  $\text{Cr}_2\text{AlC}$  and its phase relationship in the system of Cr–Al–C had been identified in 1980s [5]. Recently, theoretical calculation on  $\text{Cr}_2\text{AlC}$  were carried out by Sun et al., [6], where the results show that  $\text{Cr}_2\text{AlC}$  possesses the highest theoretical bulk modulus among  $\text{M}_2\text{AlC}$  (M=Ti, V, Cr, Nb and Ta) that is resulted from its greatest M–C bond energy. Later, the results that bulk

$\text{Cr}_2\text{AlC}$  showed an excellent oxidation resistance at 1200 °C comparing with that of  $\text{Ti}_3\text{SiC}_2$  was reported [7], further revealing that  $\text{Cr}_2\text{AlC}$  could be a promising material. In addition,  $\text{Cr}_2\text{AlC}$  ceramics were studied in our previous work, in which the electrical and thermal properties as well as phase formation sequence of  $\text{Cr}_2\text{AlC}$  were described in Refs. [8,9] respectively.

Spark Plasma Sintering (SPS), as a new sintering technique, has been employed by Zhang et al., [10] and Gao et al., [11] on the fabrication of  $\text{Ti}_3\text{SiC}_2$  and Mei et al., [12] on  $\text{TiAl/Ti}_2\text{AlC}$  composites as well as Wang et al., [13] on  $\text{Ti}_3\text{SiC}_2/\text{Al}_2\text{O}_3$  composites. It is noted that SPS technique can fabricate dense samples at low temperature with short time, whereas application of SPS on preparation of bulk  $\text{Cr}_2\text{AlC}$  has not been available in literature yet.

The purpose of this paper concerns the synthesis and densification behavior as well as the microstructure observation of  $\text{Cr}_2\text{AlC}$  samples sintered by SPS technique from coarse and fine starting powders. On the other hand, the phase assembly, microstructure and hardness of  $\text{Cr}_2\text{AlC}$  samples prepared by hot-pressing will also be presented for comparison.

## 2. Experimental procedure

There are two kinds of raw powders used as starting materials: 1) chromium ( $\sim 32 \mu\text{m}$ , 99.95%), aluminum ( $\sim 130 \mu\text{m}$ , 99.95%) and graphite ( $\sim 5 \mu\text{m}$ , 99%) powders were used as the coarse starting materials, namely CAC10; 2) chromium with small particle size ( $\sim 3 \mu\text{m}$ ), aluminum ( $\sim 3 \mu\text{m}$ , 99%) and the same graphite powders as that used in CAC10 were used as the fine starting materials, named as NCAC10. Fine chromium was obtained by milling chromium powder mentioned above for 8 h using  $\text{Si}_3\text{N}_4$  ball as milling media in planet milling machine.

The powders were weighed according to the composition  $\text{Cr}:\text{Al}:\text{C}=2:1.1:1$  and milled in absolute alcohol for 24 h using  $\text{Si}_3\text{N}_4$  ball as milling media. Dried powders were pre-pressed as pellets and sintered in SPS equipment (FCT-Systeme, Gewerbepark 11, 96528 Rauenstein, Germany) at a designed temperature for 5 min under 50 MPa with a heating rate of  $200^\circ\text{C}/\text{min}$ . Samples hot-pressed at  $1400^\circ\text{C}$  for 1 h under 20 MPa, named as HPed samples, were prepared for comparison with SPSed ones.

Density of the sintered samples was measured by Archimedes principle. Phase assemblages were determined by X-ray diffraction (XRD) with  $\text{CuK}\alpha$  radiation at 40 kV and 100 mA (D/max 2550 V, Japan). The Vickers hardness was determined by indentation using a Vickers diamond indenter and a load of 20 N for 10 s (Akashi). Microstructure observation by SEM with back-scattered electron image was performed via an electron probe microanalyzer (JEOL JXA-8100F, Japan) on the polished surface of samples.

## 3. Results and discussion

### 3.1. XRD analysis of SPSed $\text{Cr}_2\text{AlC}$ samples

The XRD patterns of samples CAC10 SPSed ranging from  $1250^\circ\text{C}$  to  $1400^\circ\text{C}$  are illustrated as Fig. 1(a)–(d), where the XRD pattern of sample HPed at  $1400^\circ\text{C}$  is also shown in Fig. 1 for comparison. For the SPSed samples,  $\text{Cr}_2\text{AlC}$  appears as a major phase, together with small

Fig. 1. XRD patterns of samples CAC10 SPSed at (a)  $1250^\circ\text{C}$ , (b)  $1300^\circ\text{C}$ , (c)  $1350^\circ\text{C}$ , (d)  $1400^\circ\text{C}$  and (e) XRD pattern of sample CAC10 HPed at  $1400^\circ\text{C}$ .

Fig. 2. XRD patterns of samples NCAC10 SPSed at (a)  $1100^\circ\text{C}$ , (b)  $1200^\circ\text{C}$ , (c)  $1300^\circ\text{C}$ , (d)  $1400^\circ\text{C}$  and (e) XRD pattern of sample NCAC10 HPed at  $1400^\circ\text{C}$ .

amount of  $\text{Cr}_7\text{C}_3$  and  $\text{Cr}_2\text{Al}$ . It is found that the amount of  $\text{Cr}_7\text{C}_3$  and  $\text{Cr}_2\text{Al}$  are comparable in the sample SPSed at  $1250^\circ\text{C}$ . When the temperature increases from  $1300^\circ\text{C}$  to  $1400^\circ\text{C}$ ,  $\text{Cr}_2\text{Al}$  content decreases quickly while the amount of  $\text{Cr}_7\text{C}_3$  goes down slowly. It is noted that the phase assembly and their content of CAC10 SPSed at  $1400^\circ\text{C}$  are very similar to those of HPed, as shown in Fig. 1(d) and (e) respectively, except for the existence of trace amount of  $\text{Cr}_2\text{Al}$  in SPSed one.

The XRD patterns of samples NCAC10 SPSed in the temperature range of  $1100$ – $1400^\circ\text{C}$  are shown in Fig. 2(a)–(d). Besides, the XRD pattern of sample NCAC10 HPed at  $1400^\circ\text{C}$  is illustrated as Fig. 2(e) for comparison. It is noticed, that there also exist three phases in samples NCAC10, just like that in samples CAC10, i.e.  $\text{Cr}_2\text{AlC}$ , as major phase, with minor amount of  $\text{Cr}_7\text{C}_3$  and trace amount of  $\text{Cr}_2\text{Al}$ , and the amount of later two phases are declined as the increment of temperature from  $1100^\circ\text{C}$  to  $1400^\circ\text{C}$ . However, it is difficult to find trace amount of  $\text{Cr}_2\text{Al}$  in HPed NCAC10 as the case of CAC10. It should be pointed out that the amount of  $\text{Cr}_2\text{AlC}$  in NCAC10 sample SPSed at  $1400^\circ\text{C}$  could reach as high as 99 wt.%, while it is 97 wt.% in SPSed CAC10 for the same temperature.

The fact that XRD results of sample NCAC10 SPSed in the temperature range of  $1200$ – $1400^\circ\text{C}$  contain close phase assembly and phase content, suggests that the reactions are almost finished at  $1200^\circ\text{C}$  and
