Keywords: CO2 storage EOR High heterogeneity High water saturation Extra-low permeability

# **ABSTRACT**

The CO<sub>2</sub> storage and CO<sub>2</sub> enhanced oil recovery (EOR) in reservoirs often face challenges due to a high heterogeneity, high levels of water saturation, or low permeability. Based on the evaluation method of the  $CO<sub>2</sub>$  storage capacity and EOR, three typical reservoirs representing these challenges are introduced to study their effect on the  $CO<sub>2</sub>$  EOR potentials and  $CO<sub>2</sub>$  storage capacities. The properties of these reservoirs were analyzed in detail, and geological models were built. The reservoir simulation method is adopted to analyze and validate the  $CO<sub>2</sub>$  injection process and the storage effect for different types of reservoirs. From the examples in this paper, the low permeability reservoirs appear to have a higher EOR potential and  $CO<sub>2</sub>$  storage capacity than highly heterogeneous reservoirs. These results support the premise of injecting CO<sub>2</sub> into reservoirs to decrease atmospheric greenhouse gas emissions while enhancing oil recovery.

# 1. Introduction

 $CO<sub>2</sub>$  flooding technology was introduced in the 1930s, and a large number of experiments and field tests were performed in the 1950s ([Gao and Yingfu, 2009](#page--1-0)). [Thomas \(1998\)](#page--1-0) proposed a  $CO<sub>2</sub>$ flooding reservoir screening criteria that considered the phase behavior characteristics, interfacial tension, flow influence, pore size distribution, wettability, and relative density of the reservoir ([Thomas, 1998\)](#page--1-0). [Sehbi et al. \(2001\)](#page--1-0) suggested that a low injection rate, a longer in-reservoir  $CO<sub>2</sub>$  retention time, and good pore structure can improve the micro-displacement efficiency ([Sehbi](#page--1-0) [et al., 2001\)](#page--1-0). [Shaw and Bachu \(2002\)](#page--1-0) developed a program to determine the applicability of different reservoirs by  $CO<sub>2</sub>$ -flooding and established the evaluation criteria for  $CO<sub>2</sub>$  EOR potential and CO2 storage capacity ([Shaw and Bachu, 2002](#page--1-0)). In 2006, [Chakravarthy et al. \(2006\)](#page--1-0) experimentally injected a polymer into the core of block fractures and improved the  $CO<sub>2</sub>$  sweep efficiency ([Chakravarthy et al., 2006\)](#page--1-0). Chen (2009) experimentally studied the  $CO<sub>2</sub>$  miscible displacement process and showed that  $CO<sub>2</sub>$  can enter the micropores and be stored there safely [\(Chen and Jishun, 2009\)](#page--1-0).

Corresponding author. E-mail address: [zhenhuarui@gmail.com](mailto:zhenhuarui@gmail.com) (Z. Rui). Wu and Shang  $(2012)$  derived a  $CO<sub>2</sub>$  storage capacity calculation model for  $CO<sub>2</sub>$  miscible flooding and showed that the storage capacity increased with an increasing cumulative gas injection and an increasing slug length ([Wu and Shang, 2012\)](#page--1-0). A number of experimental and theoretical studies suggest that the storing of  $CO<sub>2</sub>$  in subsurface reservoirs is an important way to decrease atmospheric greenhouse gas emissions ([Carbon Sequestration Leadership](#page--1-0) [Forum, 2007; Zhao and Liao, 2012\)](#page--1-0). However, the geological characteristics of real reservoirs are complex. Challenges such as CO<sub>2</sub>flooding in reservoirs arise from the complexities in reservoirs with high levels of heterogeneity, high levels of water saturation, or low permeability. Three typical reservoirs that represent these types of complexities are selected to study their respective  $CO<sub>2</sub>$  EOR potentials and  $CO<sub>2</sub>$  storage capacities. The reservoir simulation method is adopted to analyze the injection process for  $CO<sub>2</sub>$  and its effects. The Eclipse software was chosen to implement the reservoir simulation in this study.

## 2. Evaluating  $CO<sub>2</sub>$  storage mechanisms and storage capacity

## 2.1.  $CO<sub>2</sub>$  storage mechanism in reservoirs

The mechanisms for  $CO<sub>2</sub>$  storage in reservoirs can be divided into physical and chemical mechanisms ([Zhao and Liao, 2012\)](#page--1-0). Physical storage or displacement of oil includes structural, stratigraphic and residual trapping processes that occur when  $CO<sub>2</sub>$  is being injected. When injecting  $CO<sub>2</sub>$  into an underground formation, CO2 will migrate upwards because of its buoyancy. However, a layer of impermeable rock can prevent it from escaping allowing  $CO<sub>2</sub>$  to be stored safely for millions of years ([Hu, 2008\)](#page--1-0). Chemical storage mechanisms include solubility and mineral trapping. The first of these involves  $CO<sub>2</sub>$  dissolving into formation water (storage by dissolution). Mineral trapping involves the weak carbonic acid that dissolution forms reacting with other reservoir minerals to form solid carbonates. However, mineral trapping is known to only occur over very long periods ([Goodman et al., 2011; Grigg, 2002\)](#page--1-0).

# 2.2.  $CO<sub>2</sub>$  storage capacity evaluation methods in reservoirs

Based on previous work by the U.S. DOE, a new method for evaluating the effective storage capacity (Eq. (1)) was introduced by [Zhao and Liao \(2012\)](#page--1-0)

$$
M_{CO_2e} = \rho_{CO_2r} \times A \times h \times \phi \times (1 - Sw) \times S_{CO^2}
$$
 (1)

$$
S_{CO2} = C_e \times \left[ \left( (1 - S_w) \times R_f + S_w \times R_w \right) + E_f \times S_{pw} \times (1 - R_w) \right. \\ \times m_{CO2in \ water} + E_f \times (1 - S_{pw}) \times (1 - R_w) \times m_{CO2in \ oil} \right]
$$

where A is the reservoir area; h is the reservoir thickness;  $\phi$  is porosity;  $S_w$  is the initial water saturation;  $\rho_{CO2}r$  is the CO<sub>2</sub> density
