## ABSTRACT

In this work, we proposed using titanium dioxides ( $\text{TiO}_2$ ) with oxygen vacancies ( $\text{H-TiO}_2$ ) as cathode catalysts to improve the electrochemical performance of non-aqueous lithium-air batteries. Such  $\text{H-TiO}_2$  catalysts were attained by a facile heat treatment of rutile  $\text{TiO}_2$  and the existence of vacancies was confirmed by Raman spectra and X-ray photoelectron spectroscopy (XPS). It was demonstrated that due to the presence of defects which can facilitate the adsorption and dissociation of oxygen, the in-house lithium-air battery with  $\text{H-TiO}_2$  can be discharged at the current densities of 0.3 and 0.5  $\text{mA cm}^{-2}$  while maintaining the specific capacities of 3.2 and 2.8  $\text{mAh cm}^{-2}$ , respectively, much higher than those of the batteries without catalysts or with pristine rutile  $\text{TiO}_2$ . In addition, the cycling test showed that the battery with  $\text{H-TiO}_2$  can undergo 400 and 372 cycles, respectively, at the current densities of 0.3 and 0.5  $\text{mA cm}^{-2}$  with a fixed specific capacity of 0.1  $\text{mAh cm}^{-2}$  and a cutoff discharge voltage of 2.0 V.

## 1. Introduction

Lithium-air (Li-air) batteries have been proposed as the next-generation power sources for portable electronic devices and electric vehicles due to their ultra-high theoretical energy density of 11,140  $\text{Wh kg}^{-1}$  at charged state (neglecting oxygen) and 3,458  $\text{Wh kg}^{-1}$  at discharged state (considering oxygen) [1–3]. Among various types of Li-air batteries, the one using a non-aqueous electrolyte has been of great interest [7] since the pioneered works by Abraham and Jiang [5]. Although promising, the non-aqueous Li-air battery is still far from practical applications. A number of scientific and practical issues [4–6] have impeded its development. One challenge is the sluggish kinetics of oxygen reduction reaction (ORR) on the cathode [7,8], which results in poor discharge performance and cyclability. Thus, the development of efficient electrocatalysts to accelerate the ORR kinetics is urgently needed.

Up to now, a variety of electrocatalysts, including carbon materials [9–11], noble metals [12,13], perovskites [14–17] and transition metal oxides [18–22] have been investigated in non-aqueous Li-air batteries. Among them, transition metal oxides have

attracted considerable interests as promising catalysts for their defective structure, low cost and outstanding catalytic activity. Zhang et al. [23] synthesized porous  $\delta\text{-MnO}_2$  as catalyst for a Li-O<sub>2</sub> battery. They found that the  $\delta\text{-MnO}_2$  electrode exhibited a catalytic effect in the discharge process and delivered much higher specific capacities. Yan et al. [24] introduced  $\text{Co}_3\text{O}_4$  as the cathode catalyst and the cell with the  $\text{Co}_3\text{O}_4$ /carbon (80 wt. % carbon) electrode showed a longer operating life and a higher discharge capacity than did the cells without  $\text{Co}_3\text{O}_4$ . In addition to  $\text{MnO}_2$  and  $\text{Co}_3\text{O}_4$ ,  $\text{TiO}_2$  is also a commonly used metal oxide and its wide application has been demonstrated in the fields of water splitting [25], dye sensitized solar cells [26], sodium-ion [27] batteries and lithium-ion batteries [28]. Recently,  $\text{TiO}_2$  were reported as catalyst substrates [29–31] and effective catalysts [32–34] for Li-air batteries due to its superior physicochemical properties and excellent chemical stability. Zhao et al. [29–31] investigated  $\text{TiO}_2$  nanotubes as a support for electrocatalysts ( $\text{RuO}_2$  and Pt). They proved that  $\text{TiO}_2$  could reduce the side reactions and electrolyte decomposition to enhance cycle life of a Li-air battery. Agyeman et al. [32] reported that the catalytic activity of  $\text{TiO}_2$  (anatase) was enhanced by nitrogen doping. They attributed the promoted round-trip efficiency and cyclic retention to the improved  $\text{Li}^+$  chemisorption and conductivity, which resulted from the presence of the localized states on the surface of nitrogen-doped  $\text{TiO}_2$ . Kang et al. [33] compared the catalytic activity of two different  $\text{TiO}_2$

polymorphs (anatase and rutile). They found that rutile  $\text{TiO}_2$  exhibited a better catalytic activity in  $\text{Li-O}_2$  batteries, owing to its intrinsic electronic structure and surface oxidation state. Geng et al. [35] used density functional theory calculations to study the  $\text{Li}_2\text{O}_2$  deposition on rutile  $\text{TiO}_2(110)$  surfaces and found that  $\text{Li}_2\text{O}_2$  would probably wet the oxides to form amorphous thin films

instead of particles, which may facilitate the transport of charge and ions.

In the field of photocatalysis,  $\text{TiO}_2$  has been widely used due to its excellent adsorption ability of oxygen [36–38], arising from the presence of oxygen vacancies. Hence, alerting the surface oxidation state of rutile  $\text{TiO}_2$  by producing oxygen vacancies may be one way to create more active sites for ORR process, which is of particular interest in a non-aqueous  $\text{Li-air}$  battery. In the present work, rutile  $\text{TiO}_2$  with oxygen vacancies was synthesized by a facile heat treatment method and its physical and chemical characteristics as well as the electrochemical performance in non-aqueous  $\text{Li-air}$  batteries were studied systematically.

## 2. Experimental

### 2.1. Preparation of $\text{TiO}_2$ with oxygen vacancies

To create oxygen vacancies in the  $\text{TiO}_2$ , rutile  $\text{TiO}_2$  (Aladdin Industrial Inc) with particle sizes of about 100 nm was heated at  $450^\circ\text{C}$  for 2 h and followed by annealing in a furnace with argon flow from  $450^\circ\text{C}$  to  $1000^\circ\text{C}$  at a heating rate of  $5^\circ\text{C min}^{-1}$ . The  $\text{TiO}_2$  particles after heat treatment were termed as  $\text{H-TiO}_2$  hereafter.

### 2.2. Preparation of cathode and cell assembly

To prepare the cathode slurry, the nitrogen doped carbon nanotubes (NCNTs, Beijing DK Nano Technology), as-prepared
