ABSTRACT

Filamin C is an actin-crosslinking protein that is specifically expressed in cardiac and skeletal muscles. Although mutations in the filamin C gene cause human myopathy with cardiac involvement, the function of filamin C *in vivo* is not yet fully understood. Here we report a medaka mutant, *zacro* (*zac*), that displayed an enlarged heart, caused by rupture of the myocardiac wall, and progressive skeletal muscle degeneration in late embryonic stages. We identified *zac* to be a homozygous nonsense mutation in the *filamin C* (*flnc*) gene. The medaka filamin C protein was found to be localized at myotendinous junctions, sarcolemma, and Z-disks in skeletal muscle, and at intercalated disks in the heart. *zac* embryos showed prominent myofibrillar degeneration at myotendinous junctions, detachment of myofibrils from sarcolemma and intercalated disks, and focal Z-disk destruction. Importantly, the expression of γ-actin, which we observed to have a strong subcellular localization at myotendinous junctions, was specifically reduced in *zac* mutant myotomes. Inhibition of muscle contraction by anesthesia alleviated muscle degeneration in the *zac* mutant. These results suggest that filamin C plays an indispensable role in the maintenance of the structural integrity of cardiac and skeletal muscles for support against mechanical stress.

Introduction

Skeletal muscle and heart are the organs that produce physical force by muscle contraction, and muscle fibers are incessantly exposed to strong mechanical stress. To protect intracellular structures against such mechanical stress, muscle fibers express a variety of muscle-specific proteins that often form large complexes.

Two major protein complexes, the dystrophin-associated glycoprotein complex (DGC) and the integrin complex are known to have important roles in affording mechanical integrity to striated muscle. In skeletal muscle, these complexes, which are localized at the sarcolemma (Arahata et al., 1988; Mayer, 2003; Watkins et al., 1988) and myotendinous junctions (MTJs; (Bao et al., 1993; Samitt and Bonilla, 1990; Shimizu et al., 1989), where the muscle fibers are connected to tendon, link the subsarcolemmal actin cytoskeleton to the extracellular matrix (ECM) (Burkin and Kaufman, 1999; Campbell, 1995; Yoshida et al., 2000). Defects in the components of this DGC lead to muscular dystrophy (Bonnemann et al., 1995; Hoffman et al., 1987; Lim et al., 1995; Nigro et al., 1996; Noguchi et al., 1995; Roberds et al., 1994), an inherited muscular disorder characterized by progressive muscle degeneration, suggesting the importance of this linkage system for the integrity of muscle fibers. Muscle fibers specifically express α7β1 integrin, and a defect of α7 integrin causes muscular dystrophy, primarily affecting muscle fibers close to the MTJs (Hayashi et al., 1998; Mayer et al., 1997; Miosge et al., 1999), pointing to the importance of the integrin-based linkage for muscle integrity, particularly at MTJs. In heart, DGC and integrins are localized at the sarcolemma as well as at intercalated disks, which are the contact sites between cardiomyocytes (Anastasi et al., 2009; van der Flier et al., 1997).

The Z-disk is a huge multi-protein complex that constitutes the border of individual sarcomeres. This Z-disk plays a key role in the crosslinking of actin thin filaments of myofibrils to withstand the extreme mechanical force generated during muscle contraction. Z-disks are attached to the sarcolemmal DGC and integrin complexes at the sites of costameres via Z-disk-associated linker molecules (Ervasti, 2003). Recently, mutations in genes encoding Z-disk components have been found to be responsible for a group of muscle diseases termed myofibrillar myopathy, which is pathologically characterized by myofibrillar disorganization, including the degeneration of the

sarcomere structure (Selcen, 2008; Selcen et al., 2004). These reports suggest that Z-disk proteins have important roles in maintaining organized sarcomere structures.

Filamins are actin-crosslinking proteins first purified by their ability to bind and precipitate actin (Hartwig and Stossel, 1975; Stossel and Hartwig, 1975). Filamins are composed of 3 isoforms, filamins A, B, and C. All filamins consist of an N-terminal actin-binding domain followed by 24 immunoglobulin-like repeats, and they dimerize at the 24th repeat domain located at the C-terminus (Stossel et al., 2001). Filamins directly interact with more than 30 diverse proteins, and are involved in multiple cellular processes including cell–cell and cell–matrix adhesion, mechanoprotection, actin remodeling, and various intracellular signaling pathways (Feng and Walsh, 2004). Filamin C is a muscle-specific isoform and localizes at MTJs, costameres, Z-disks, and intercalated disks in mammal and avian muscles (Ohashi et al., 2005; van der Ven et al., 2000a). Interestingly, filamin C interacts with both DGC (Thompson et al., 2000) and integrin (Gontier et al., 2005; Loo et al., 1998), as well as with the Z-disk proteins myotilin (van der Ven et al., 2000b), FATZ-1 (Faulkner et al., 2000), and myopodin (Linnemann et al., 2010) through its C-terminal region. Such localization and protein interaction suggest that filamin C functions in maintaining the mechanical integrity of muscle cells. Recently, mutations in the filamin C gene were identified in patients having myofibrillar myopathy (Kley et al., 2007; Luan et al., 2010; Shatunov et al., 2009; Vorgerd et al., 2005). These patients frequently develop cardiac abnormalities in addition to skeletal myopathy, suggesting the essential role of filamin C in both skeletal and cardiac muscles. To investigate the function of filamin C *in vivo*, Dalkilic et al. (2006) generated *filamin C*-deficient mice having a deletion of the last 8 exons of *Flnc*. This deficient mouse shows fewer muscle fibers or primary myotubes than normal and abnormal rounded fibers, suggesting defects in primary myogenesis; however, this mouse does not present any cardiac defects, which indicates a partial-loss-of-function. Since these mice die *in utero* or live only a short while after birth, further detailed observations cannot be carried out.

Recently, zebrafish have emerged as an alternative model organism to study the vertebrate muscular system and to isolate new dystrophy-causing genes/pathways (Guyon et al., 2007; Steffen et al., 2007). A deficiency of DGC or integrin-linked kinase causes a muscular dystrophic phenotype in zebrafish embryos (Bassett et al., 2003; Cheng et al., 2006; Gupta et al., 2011; Guyon et al., 2005; Postel et al., 2008), suggesting that their functions are likely to be analogous to those in humans. In zebrafish embryos, the DGC is localized initially at the junctional area, where the ends of muscle fibers attach to the myosepta, corresponding to the myotendinous junction (MTJ). Loss of DGC causes muscle fiber detachment at MTJs, indicating compromised adhesion between muscle fibers and the ECM of myosepta. Medaka (*Oryzias latipes*), another teleost fish, has the experimental advantages of external development, transparency, and quick production of a number of embryos, similar to the zebrafish. Unlike zebrafish, however, various medaka inbred strains have been established; and the medaka genome, which is about one-half of the size of the zebrafish genome, is almost fully sequenced and aligned, indicating that the medaka has powerful advantages for the application of forward genetics (Ishikawa, 2000; Wittbrodt et al., 2002).

Here, we identified a medaka mutant, *zacro* (*zac*), that has a nonsense mutation, resulting in an early truncation at the 15th immunoglobulin-like repeat of the medaka orthologue of filamin C. This mutation causes myocardiac rupture in the ventricle. Although this mutant displayed normal myogenesis in myotome muscles during early stages of embryonic development, its myofibrils gradually degenerated and became disorganized in later stages. Detailed histological analysis suggests an indispensable role of filamin C in the maintenance of the muscle structure rather than in its formation in both heart and skeletal muscles.

Materials and methods

Medaka strains and mutant screening

All studies requiring wild-type medaka (*O. latipes*) were carried out by using the Qurt strain, which was derived from the southern population (Wada et al., 1998). Fish were maintained in an aquarium system with re-circulating water at 28.5 °C. Embryos were obtained from natural spawning, and incubated at 28 ± 2 °C. Stages were determined as previously described (Iwamatsu, 2004). *N*-ethyl-*N*-nitrosourea (ENU) was used for mutagenesis, and a standard genetic F3 screening for mutations affecting embryogenesis were performed as described earlier (Ishikawa, 1996; Ishikawa et al., 1999). The *zac* mutant was identified by microscopic inspection as a Mendelian-inherited recessive lethal mutation that caused a phenotype characterized by congestion in the blood vessels and pericardial edema.

Positional cloning

zac heterozygous fish, which were maintained on the southern Qurt genomic background, were mated with the northern HNI strain fish (Hyodo-Taguchi, 1980) to generate F1 families. Embryos for the genetic mapping were obtained from inter-crosses of F1 *zac* carriers. To locate the genetic linkage, we conducted bulk segregant analysis on pools of genomic DNA from *zac* mutants and wild-type embryos by using sequence tagged site (STS) markers on the medaka genome (Kimura et al., 2004). The *zac* region was narrowed down by using additional STS markers, AU171271 and Olb2110h (Naruse et al., 2000), and newly designed restriction fragment length polymorphism (RFLP) markers, HAL and KCND2 (HAL; 5′-GGATGGGCAGATGCCAAATATG-3′ and 5′-GTCCCGTTGATCAGAGCCAG-3′/MboI, KCND2; 5′-CAGCAGGTGTAGCGGCATG-3′ and 5′-GTTGGCCATCACTGATATGGC-3′/AfaI). cDNAs of *flnc* from *zac* mutant and wild-type embryos were amplified, and verified by sequencing. The full-length cDNA of *flnc* was cloned by PCR using primers including XbaI restriction enzyme sites [5′-CAATCTAGACAAGGAACAAGCC-3′ and 5′-GAATCTAGACCACCATTTAGCC-3′], and was sequenced. We obtained 2 different *flnc* clones, which appeared to be splice variants. To confirm the linkage between the *zac* mutation and *flnc* gene, we performed allele-specific PCR using 2 independent outer primers [5′-TTCAGTTGGAGGACATGGGAT-3′ and 5′-GACACCTGCAACACAACTCTA-3′] in combination with either a wild type-specific antisense primer [5′-CTTGCAGGTCACCTTTCCTTT-3′] or a mutant-specific one [5′-CTTGCAGGTCACCTTTCCTTA-3′]. We also performed 5′-RACE and 3′-RACE to obtain full-length sequence information on *flnc* cDNA. The sequences of the medaka *flnc* have been deposited in GenBank under the accession numbers AB639344 and AB639345.

Birefringence assay

Embryos were dechorionated at stage 27. Muscle birefringence was analyzed at stages 32 and 34 by placing anesthetized embryos on a glass dish and observing them with an underlit dissecting scope (Olympus, SZX12) having 2 polarizing filters (Olympus, SZX-P0 and SZX2-AN). The top polarizing filter was twisted until only the light refracting through the striated muscle was visible.

Histological analysis

Embryos were fixed overnight at 4 °C in 4% paraformaldehyde (PFA) in phosphate-buffered saline pH 7.4 (PBS), dehydrated by ethanol, and embedded in a resin (Technovit 8100, Kulzer Heraeus) according to the manufacturer's instructions. Sections were cut at 2 μm and stained with Harris's hematoxylin and Eosin Y or Masson trichrome staining buffer (SIGMA).
