ABSTRACT

Saroglitazar is a dual PPAR $\alpha/\gamma$ agonist approved in India for the management of diabetic dyslipidemia.

*Aims:* The objective of this study was to evaluate the safety and efficacy of saroglitazar 4 mg once daily in clinical practice.

*Methods:* This was an observational, multicenter, single-arm study. Patients with type 2 diabetes (with on-going antidiabetic medication), age above 18 years, and triglycerides $\geq$200 mg/dL were included.

*Results:* A total 2804 patients with a mean duration of diabetes 6.29 yrs were included in this analysis. The baseline demographic profile was: mean age of 53 yrs, mean body weight 72.3 kg and mean BMI of 27 kg/m$^2$. 62.5% patients were male and 57.8% were reported to be on statin therapy at baseline. All 2804 patients were on antidiabetic medications with 15.4% patients on monotherapy and rest were on two or more than two antidiabetic medications at baseline. The baseline triglycerides and HbA1C values were 312.3 mg/dL and 8.3% respectively. At 3 months follow-up, use of saroglitazar 4 mg led to significant reduction in TG (35.8%), LDL-C (16.4%), total cholesterol (19%) and non-HDL-C (23.4%). Addition of saroglitazar to baseline antidiabetic medications showed a significant 0.9% absolute reduction in HbA1c with significant improvement in fasting and post prandial plasma glucose. No serious adverse events, alteration in liver or renal enzymes and edema or weight gain were reported.

*Conclusion:* Saroglitazar is a potential therapeutic option in type 2 diabetic patients with high TG levels, not controlled by statins, for comprehensive control of lipid and glycemic parameters with acceptable safety profile.

## 1. Introduction

The cardiovascular diseases (CVDs) burden globally and as well in India is rising sharply and presently is the number one cause of mortality.[1] INTERHEART study, a major Canadian-led global study identified 9 easily measured risk factors (smoking, lipids, hypertension, diabetes, obesity, diet, physical activity, alcohol consumption, and psychosocial factors) that account for over 90% of the risk of acute myocardial infarction (AMI) and dyslipidemia being the strongest risk predictor globally.[2] Diabetic dyslipidemia (DD) is an important factor contributing to the increased risk of CVDs.[3] Studies have shown that three out of four diabetes patients globally have associated dyslipidemia.[4] DD, also known as atherogenic dyslipidemia, is the triad of high triglycerides (TG), higher proportion of small dense low density lipoprotein cholesterol (sd-LDL-C) and low high density lipoprotein cholesterol (HDL-C).[5] Currently statins, fibrates, niacin and omega 3 fatty acids are the available drugs in the armamentarium for the treatment of dyslipidemia. Saroglitazar is the novel molecule approved in India for the management of DD. It is the first dual peroxisome proliferator activated receptor (PPAR)-$\alpha/\gamma$ agonist to have successfully completed its clinical research and to be approved for clinical use anywhere in the world. In previous studies, saroglitazar has shown significant benefit in terms of improvement in lipid and glycemic parameters with good safety profile. There has been a 46.7% decrease in TG, 32.5% decrease in non-HDL-C, 0.3% absolute reduction in glycosylated hemoglobin (HbA1c) with saroglitazar 4 mg in Indian DD patients.[6,7] The present observational study was done to evaluate the safety and efficacy of saroglitazar in Indian DD patients in clinical practice.

## 2. Methodology

This was an observational, multicenter, single-arm, post marketing study of saroglitazar 4 mg in Indian DD patients (at outpatient clinic settings) who were prescribed saroglitazar 4 mg once daily as per the approved indication (diabetic dyslipidemia and hypertriglyceridemia in type 2 diabetes not controlled with statin). Only patients who qualified for saroglitazar treatment as per treating physician's clinical judgment (as per prescribing information of saroglitazar) in outpatient settings were included in this analysis. There was no experimental intervention done. Patients with type 2 diabetes (with on-going antidiabetic medication), age above 18 years and triglycerides $\geq$200 mg/dL were included. The exclusion criteria were pregnancy, lactating mothers, active liver disease, NYHA class III or IV heart failure, malignancy, or patients with history of hypersensitivity to saroglitazar or any of the excipients used in the formulation. The data were collected from the treating physicians who had prescribed saroglitazar between November 2013 and July 2014. In this observational analysis, 3133 patient data were obtained and only those with antidiabetic medications recorded at baseline were included in the final analysis. Antidiabetic medications at baseline were not reported in 329 patients, hence 2804 patient data were considered. All these 2804 patients were prescribed tablet saroglitazar 4 mg once daily before breakfast. Baseline and 3 month glycemic parameters (HbA1c, Fasting plasma glucose, post-prandial plasma glucose), lipid parameters (total cholesterol, LDL-C, HDL-C, TG, non-HDL-C) and adverse event if any reported were recorded. The laboratory tests were conducted at centers recommended by treating physicians. The LDL-C values are direct, not calculated from Friedewald equation. Non-HDL-C was calculated by subtracting HDL-C value from total cholesterol value. Only those patient data which had both baseline and 3 month follow up data were considered for individual laboratory parameters analysis (e.g. in Table 4, for the analysis of effect on TG, out of the total 2804 patient data, 2767 were used for analysis as they had both baseline and 3 month follow up TG values recorded). The SAS® system for Windows (release 9.3; SAS Institute) was used for statistical analysis. Significant differences in the means from baseline to post baseline were assessed by paired *t*-tests. "*p*" value of <0.05 was considered as significant.

## 3. Results

The data of 3133 patients prescribed saroglitazar 4 mg once daily was recorded at baseline and at 3 months and analyzed. All were type 2 diabetes patients with average duration of diabetes of 6.29 years. The mean age of the patients was 53 years and 62.5% of the patients were male. The patients had a mean weight of 72.3 kgs and a mean body mass index of 27.0 kg/m$^2$ (Table 1). Out of 3133 patients, 284 were reported to have history of coronary heart disease.

In this study 57.8% of patients were reported to be on statin therapy, with atorvastatin being the most commonly used statin (69.6%), at the time of entry (Table 2). All patients were advised to continue on-going statin therapy and saroglitazar 4 mg once daily was prescribed as 2nd line lipid-lowering agent.

Out of 3133 patients, concomitant antidiabetic medications at baseline were recorded in 2804 patients (89.5%) and only these patient data were utilized for further analysis. Saroglitazar 4 mg was prescribed in addition to on-going single antidiabetic therapy in 15.4%, to on-going dual antidiabetic therapy in 43.4% and in addition to more than two on-going antidiabetic therapy in 41% of the patients (Table 3a and b). In the study population ($n$ = 2804), the most commonly reported antidiabetic drug at baseline was metformin in 79.3% of the patients, followed by sulphonylureas in 60.2%, gliptins in 31.1%, alpha glucosidase inhibitors in 18.90%, insulin in 14.7%, thiazolidinediones in 6.5%, meglitinide analogs in 0.9%, GLP 1 agonist 0.2% and bromocriptine in <1% (Table 3c).

**Table 1 – Demographic profile of patients (N = 3133).**

| | |
|---|---|
| Age (years); $n$ = 3100 | 53 ± 10 |
| Male | 1958 (62.5%) |
| Weight (kg); $n$ = 2737 | 72.3 ± 11.45 |
| BMI (kg/m$^2$); $n$ = 2565 | 27.0 ± 4.17 |
| Average duration of diabetes (years); $n$ = 2562 | 6.29 ± 6.20 |

Data are mean ± SD values or number (%) as indicated. **Abbreviations**: N = number of subjects in specified treatment; $n$ = number of subjects at specified category; BMI = body mass index. Data Determined at baseline.
