

# Systemic lupus erythematosus—associated neutrophilic dermatosis with palmoplantar involvement

Nicola A. Quatrano, MD, Maressa C. Criscito, BS, Alisa N. Femia, MD, and Nooshin K. Brinster, MD  
New York, New York

**Key words:** autoimmune connective-tissue disorders; neutrophilic dermatosis; neutrophils; nonbullous; palmoplantar; systemic lupus erythematosus.

## INTRODUCTION

Neutrophilic infiltrates in the setting of systemic lupus erythematosus (SLE) are commonly associated with bullous or vasculitic disease. Recently, an increasing number of reports describe a nonbullous, nonvasculitic SLE-associated neutrophilic dermatosis. Prior cases of SLE-associated neutrophilic dermatosis describe an urticarial eruption involving the trunk and extremities. Here we report the case of a 27-year-old woman with SLE-associated neutrophilic dermatosis with palmoplantar involvement, thus, expanding the clinical spectrum of this disease. Neutrophilic dermatosis may represent the initial cutaneous manifestation of systemic disease in one-third of patients. Thus, prompt recognition of this distinct cutaneous entity should promote screening for SLE.

## CASE REPORT

A 27-year-old woman with a 9-month history of SLE was admitted to the hospital with 4 days of worsening pleuritic chest pain, dyspnea, and arthralgias. She also had a 1-day history of a burning, annular eruption on her trunk, palms, and soles. Upon admission, the patient was found to have recurrent pericardial and bilateral pleural effusions in the setting of an acute SLE flare. Although complete blood count and basic metabolic panel were unremarkable, the patient's anti-double-stranded DNA antibody was 266 IU/mL, C3 was 41.4 mg/dL (laboratory-specific reference range, 90–180 mg/dL), and C4 was 6.62 mg/dL (laboratory-specific reference range, 10–40 mg/dL).

### Abbreviations used:

BMZ:	basement membrane
DEJ:	dermoepidermal junction
DIF:	direct immunofluorescence
LE:	lupus erythematosus
SLE:	systemic lupus erythematosus

From prior workup of SLE, antinuclear antibody was 1:640 with speckled pattern and was anti-Smith antibody positive and antiribonucleoprotein antibody positive. Anti-SS-A antibody was 7.3 (normal <0.9 antibody index) and anti-SS-B antibody was 0.6 (normal <0.9 antibody index). Erythrocyte sedimentation rate was 45 mm/h.

On physical examination, the patient had blanchable, erythematous macules and annular, urticarial papules and plaques bilaterally distributed on the palmoplantar surfaces (Fig 1). Additionally, there were faint, blanchable, erythematous macules on the chest and back. Shave biopsy findings of the left plantar surface showed neutrophils aligned along the dermoepidermal junction (DEJ) associated with vacuolar alteration and rare dyskeratosis (Fig 2). There was also a superficial, perivascular, and interstitial predominantly neutrophilic infiltrate with lymphocytes and leukocytoclasia, without vasculitis or a significant increase in dermal mucin (Fig 3).

At the time of presentation, the patient was taking hydroxychloroquine (200 mg twice daily), prednisone (50 mg/d), omeprazole, atovaquone, and cholecalciferol. She was treated with intravenous methylprednisolone and underwent a thoracentesis

with improvement in respiratory status and resolution of chest pain. Palmoplantar surfaces were treated with clobetasol ointment twice daily with only modest improvement; however, shortly after an increase in systemic glucocorticoids and the initiation of mycophenolate mofetil, the eruption subsided. At 5-month follow-up, the patient remained free of the cutaneous eruption while maintained on hydroxychloroquine (200 mg twice daily) and mycophenolate mofetil (1500 mg twice daily). Methylprednisolone had been tapered down to 10 mg daily.

## DISCUSSION

Ackerman was among the first to consider SLE in the histologic differential diagnosis of nonbullous, nonvasculitic neutrophilic inflammatory dermatosis.<sup>1,2</sup> He described the presence of neutrophils and neutrophilic dust immediately beneath the epidermis of an interface dermatitis and postulated that these histopathologic features may represent a “muted” expression of bullous SLE.<sup>2</sup> The first clinical

**Fig 3.** Neutrophil-mediated vacuolar alteration along the DEJ with a necrotic keratinocyte. There is also a perivascular and interstitial neutrophilic infiltrate with leukocytoclasia in the absence of vasculitis. (Hematoxylin-eosin stain.)

case of SLE associated with a Sweet’s syndrome–like dermatosis was reported in 1985.<sup>3</sup> Since then, close to 50 cases of SLE-associated neutrophilic dermatosis distinct from Sweet’s syndrome, pyoderma gangrenosum, and bullous lupus erythematosus (LE) have been reported.<sup>3-8</sup>

The literature on neutrophil-dominant manifestations of SLE is fraught with confusion, in part because of the overlap in terminology. A variety of terms have been used to describe nonbullous, nonvasculitic, neutrophilic dermatosis and include nonbullous neutrophilic dermatosis, nonbullous neutrophilic LE, Sweet’s syndrome–like neutrophilic dermatosis, and SLE-associated neutrophilic dermatosis. However, reproducible clinical and histopathologic reports confirm that SLE-associated neutrophilic dermatosis represents a distinct entity that is closely associated with and may herald the development of systemic disease.<sup>4-8</sup> Clinical and histopathologic differential diagnoses of SLE-associated neutrophilic dermatosis are vast (Table 1).<sup>8-10</sup> Although there are no known prognostic or therapeutic differences for SLE-associated neutrophilic dermatosis, recognition of this distinct cutaneous entity should prompt screening for SLE.

The cutaneous findings of SLE-associated neutrophilic dermatosis include erythematous papules and plaques, many of which are described as urticarial and some of which have an annular morphology, most commonly involving the trunk and extremities, and without bulla formation or mucosal involvement.

Histopathologic features include an interstitial and perivascular predominantly neutrophilic infiltrate with leukocytoclasia and variable vacuolar alteration along the DEJ, without the presence of vasculitis or bullae.<sup>5</sup> The degree of neutrophilic infiltrate varies from paucicellular to cell rich Sweet’s syndrome like, which suggests a spectrum
