Unsaturated amine  
Rare earth metal oxides

## ABSTRACT

Vapor-phase catalytic dehydration of 5-amino-1-pentanol was investigated over various oxide catalysts including rare earth oxides (REOs). Over ordinary acidic oxides such as  $\text{Al}_2\text{O}_3$ ,  $\text{SiO}_2$ ,  $\text{SiO}_2\text{-Al}_2\text{O}_3$ ,  $\text{TiO}_2$ , and  $\text{ZrO}_2$ , a cyclic amine such as piperidine was mainly produced at temperatures of 300 °C and higher. In contrast, basic REOs with a cubic bixbyite structure showed the catalytic activity in the conversion of 5-amino-1-pentanol to produce 4-penten-1-amine at 425 °C. In REO catalysts,  $\text{Tm}_2\text{O}_3$ ,  $\text{Yb}_2\text{O}_3$ , and  $\text{Lu}_2\text{O}_3$  showed the high conversion of 5-amino-1-pentanol and the high selectivity to 4-penten-1-amine. Especially,  $\text{Yb}_2\text{O}_3$  calcined at 800 °C showed a high formation rate of 4-penten-1-amine with the selectivity of ca. 90% at 425 °C. In comparing the reactivity of several amino alcohols to form the corresponding unsaturated amines,  $\text{Yb}_2\text{O}_3$  effectively catalyzed the dehydration of 6-amino-1-hexanol into 5-hexen-1-amine, whereas 3-amino-1-propanol and 4-amino-1-butanol were not effectively dehydrated due to the decomposition of the reactant.

## 1. Introduction

Unsaturated amines, which have both a carbon double bond and an amino group in the molecule, can be used for various applications such as polymer, ion-exchange membrane, raw material of chemical, pharmaceutical and agricultural chemical intermediates. As a pioneering report, Zimmermann et al. have reported that unsaturated amines can be produced by hydroaminomethylation of olefins using three gases such as  $\text{H}_2$ ,  $\text{CO}$ , and  $\text{NH}_3$  [1]. In the method, however, the resulting primary amines are further converted into the secondary amine. Nicolai et al. have showed that 4-penten-1-amine is produced by reduction of 4-pentenamido [2], while 4-penten-1-amine is produced with a low yield, which is approximately 40%.

We have previously reported a novel catalytic synthesis process of unsaturated alcohols via the dehydration of alkanediols such as 1,5-pentanediol [3–5], 1,4-butanediol [5–8], and 1,3-butanediol [5,9–11] over rare earth oxides (REOs) calcined at 800 °C. In the dehydration of 1,5-pentanediol, heavy REOs such as  $\text{Lu}_2\text{O}_3$ ,  $\text{Yb}_2\text{O}_3$ , and  $\text{Tm}_2\text{O}_3$  are highly active and selective for the formation of 4-penten-1-ol, and the highest selectivity of 4-penten-1-ol was 80.3% over  $\text{Tm}_2\text{O}_3$  calcined at 800 °C [4,5]. It is also known that REOs [12,13] as well as  $\text{ZrO}_2$  [14–16] and  $\text{CeO}_2$ -

$\text{ZrO}_2$  [17] have unique character to catalyze the dehydration of 2-alcohol to produce  $\alpha$ -olefin via Hoffman elimination. We have also reported the dehydration of 1,4-butanediol as well as 1,5-pentanediol over composite oxides of cubic  $\text{Sc}_{2-x}\text{Yb}_x\text{O}_3$  ( $x = 0.5, 1.0$ , and 1.5) [18]: the highest selectivity to 3-buten-1-ol surpassed 80% in the dehydration of 1,4-butanediol over the  $\text{Sc}_{2-x}\text{Yb}_x\text{O}_3$  ( $x = 0.5, 1.0$ , and 1.5) catalysts calcined at 800 °C. Thus, we expected that REOs could work effectively in the dehydration of amino alcohols.

In this work, we investigated the dehydration of 5-amino-1-pentanol into 4-penten-1-amine over REOs and  $\text{Sc}_{2-x}\text{Yb}_x\text{O}_3$  ( $x = 0.5, 1.0$ , and 1.5) at 425 °C to search a suitable catalyst and the efficient reaction conditions. We have found that 4-penten-1-amine is efficiently produced over  $\text{Tm}_2\text{O}_3$ ,  $\text{Yb}_2\text{O}_3$ , and  $\text{Lu}_2\text{O}_3$  in the dehydration of 5-amino-1-pentanol (Scheme 1). We also investigated the catalytic features of  $\text{Yb}_2\text{O}_3$  in the dehydration of 5-amino-1-pentanol. Furthermore, we performed other amino alcohols with different carbon chain length, such as 3-amino-1-propanol, 4-amino-1-butanol, and 6-amino-1-hexanol, to produce the corresponding unsaturated amines over  $\text{Yb}_2\text{O}_3$ .

**Scheme 1.** Dehydration of 5-amino-1-pentanol to 4-penten-1-amine.

Tm(NO<sub>3</sub>)<sub>3</sub>, Yb(NO<sub>3</sub>)<sub>3</sub>, Lu(NO<sub>3</sub>)<sub>3</sub>, and Sc(NO<sub>3</sub>)<sub>3</sub>, were purchased from Sigma-Aldrich Co., Ltd., Japan. La<sub>2</sub>O<sub>3</sub>, Pr<sub>6</sub>O<sub>11</sub>, Mg(NO<sub>3</sub>)<sub>2</sub>, Ca(NO<sub>3</sub>)<sub>2</sub>, and Dy(NO<sub>3</sub>)<sub>3</sub> hexahydrate were purchased from Wako Pure Chemicals Co., Japan. 5-Amino-1-pentanol, 3-amino-1-propanol, and 4-amino-1-butanol were purchased from Wako Pure Chemicals Co., Japan. 6-Amino-1-hexanol aqueous solution (70 wt.%) was purchased from Sigma-Aldrich Co., Ltd., Japan.

Except La<sub>2</sub>O<sub>3</sub> and Pr<sub>6</sub>O<sub>11</sub>, other REOs such as CeO<sub>2</sub>, Nd<sub>2</sub>O<sub>3</sub>, Sm<sub>2</sub>O<sub>3</sub>, Eu<sub>2</sub>O<sub>3</sub>, Gd<sub>2</sub>O<sub>3</sub>, Tb<sub>2</sub>O<sub>3</sub>, Dy<sub>2</sub>O<sub>3</sub>, Ho<sub>2</sub>O<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, Er<sub>2</sub>O<sub>3</sub>, Tm<sub>2</sub>O<sub>3</sub>, Yb<sub>2</sub>O<sub>3</sub>, Lu<sub>2</sub>O<sub>3</sub>, and Sc<sub>2</sub>O<sub>3</sub> were prepared by the calcination of the corresponding nitrate. MgO and CaO were also prepared by the calcination of the corresponding nitrate. Monoclinic Yb<sub>2</sub>O<sub>3</sub> was supplied by Kanto Kagaku Co., Ltd., Japan. Three Sc<sub>2-x</sub>Yb<sub>x</sub>O<sub>3</sub> (x = 0.5, 1.0, and 1.5) catalysts were supplied by Daiichi Kigenso Kagaku Kogyo Co., Ltd., Japan [18]. Rutile TiO<sub>2</sub> (JRC-TIO-3) and anatase TiO<sub>2</sub> (JRC-TIO-4) were supplied by Catalyst Reference of Japan. Amorphous SiO<sub>2</sub> (CARIACT Q10) was supplied by Fuji Sillycia Chemical Ltd. Monoclinic ZrO<sub>2</sub> (RSC HP) and tetragonal ZrO<sub>2</sub> were supplied by Daiichi Kigenso Kagaku Kogyo Co., Ltd., Japan and Saint-Gobain, respectively. Al<sub>2</sub>O<sub>3</sub> (N611N) and SiO<sub>2</sub>-Al<sub>2</sub>O<sub>3</sub> (N631L) were purchased from Nikki Chemical Co., Ltd., Japan.

## 2.2. Catalytic reaction

The dehydration of amino alcohols, such as 5-amino-1-pentanol, 3-amino-1-propanol, 4-amino-1-butanol, and 6-amino-1-hexanol, were carried out in a fixed-bed down flow reactor with an inside diameter of 20 mm under the atmospheric pressure of either N<sub>2</sub> or H<sub>2</sub> gas. In each test, 0.5 g of catalyst was loaded

into the reactor. Amino alcohols were dehydrated at temperatures between 300 and 450 °C. Prior to the reaction, the catalyst was preheated in the flow reactor in a carrier gas at the same temperature as the reaction temperature for 1 h. After the pretreatment, an amino alcohol was fed through the top of the reactor at a liquid feed rate of 1.71 cm<sup>3</sup> h<sup>-1</sup>, which corresponds to 16 mmol h<sup>-1</sup> for 5-amino-1-pentanol and  $W/F = 31 \text{ g}_{\text{cat.}} \text{ h mol}^{-1}$  where  $W$  is catalyst weight and  $F$  is a reactant feed rate, together with a carrier gas flow of 20 cm<sup>3</sup> min<sup>-1</sup>. An effluent mixture collected every hour was analyzed by gas chromatography (GC-8A, Shimadzu, Japan) with a capillary column of TC-5 (30m, GL Science Inc., Japan) over a temperature range controlled from 70 to 280 °C at a heating rate of 10 °C min<sup>-1</sup>. The major products in the dehydration were 4-penten-1-amine, piperidine, tetrahydropyridine,  $\delta$ -valerolactam, and  $n$ -pentyl amine.

Since the catalytic activity is stable in the similar manner to the previous works reported in the dehydration of diols [3–11], the conversion of 5-amino-1-pentanol and the selectivity to each product were averaged in the 1–5 h to evaluate the catalytic activity. The formation rate of the corresponding unsaturated amines per unit surface area [mmol h<sup>-1</sup> m<sup>-2</sup>] was calculated by using the feed rate of the reactant multiplied by the conversion and the selectivity divided by the catalyst weight and specific surface area.

## 2.3. Characterization

The specific surface area (SA) of each catalyst was calculated by the BET method using the N<sub>2</sub> isotherm at –196 °C. X-ray diffraction (XRD) patterns were recorded on an XRD7000 (Shimadzu, Japan) using Cu K $\alpha$  radiation ( $\lambda = 0.15 \text{ nm}$ ) to detect the crystal structure of the samples. The tube voltage and current were 40 kV and 40 mA, respectively.

Temperature-programmed desorption (TPD) of adsorbed CO<sub>2</sub> was measured to estimate the basicity of the catalysts. The numbers of basic sites were estimated from neutralization–titration curves of diluted NaOH solution [19,20]. Prior to the CO<sub>2</sub> adsorption, a sample (ca. 50 mg) was preheated in a quartz tube at 500 °C for 1 h under a reduced pressure. In CO<sub>2</sub>-TPD, CO<sub>2</sub> was adsorbed on the sample at room temperature for 72 h and evacuated for 1 h. After no CO<sub>2</sub> had been observed in N<sub>2</sub> flow at room temperature, the sample was heated from room temperature to 800 °C at a heating rate of 10 °C min<sup>-1</sup> in an N<sub>2</sub> flow of 34 cm<sup>3</sup> min<sup>-1</sup>. The desorbed CO<sub>2</sub> molecules, together with N<sub>2</sub> gas, were bubbled into an electric conductivity cell containing a dilute NaOH solution (50 cm<sup>3</sup>). The conductivity of the solution was monitored, and the resulting conductivity curve was differentiated to provide a distribution curve of CO<sub>2</sub> desorbed from adsorbent.

## 3. Results

### 3.1. Characterization of REOs

Fig. 1 shows the XRD patterns of REOs and Sc<sub>2-x</sub>Yb<sub>x</sub>O<sub>3</sub> calcined at 800 °C. REO samples had different crystal structures with A-, B-, C-, and C<sub>F</sub>-type [21,22]. Light REOs such as La<sub>2</sub>O<sub>3</sub>, Pr<sub>6</sub>O<sub>11</sub>, and Nd<sub>2</sub>O<sub>3</sub> had a hexagonal structure of A-type. Other light REOs such as Sm<sub>2</sub>O<sub>3</sub> had a monoclinic structure of B-type. On the other hand, heavy REOs such as Gd<sub>2</sub>O<sub>3</sub>, Tb<sub>4</sub>O<sub>7</sub>, Dy<sub>2</sub>O<sub>3</sub>, Ho<sub>2</sub>O<sub>3</sub>, Y<sub>2</sub>O<sub>3</sub>, Er<sub>2</sub>O<sub>3</sub>, Tm<sub>2</sub>O<sub>3</sub>, Yb<sub>2</sub>O<sub>3</sub>, Lu<sub>2</sub>O<sub>3</sub>, Sc<sub>2</sub>O<sub>3</sub>, and Sc<sub>2-x</sub>Yb<sub>x</sub>O<sub>3</sub> (x = 0.5, 1.0, and 1.5) [18] had a cubic bixbyite structure of C-type. Eu<sub>2</sub>O<sub>3</sub> had an unknown phase, and CeO<sub>2</sub> had a cubic fluorite structure of C<sub>F</sub>-type. The crystal phases of REOs and Sc<sub>2-x</sub>Yb<sub>x</sub>O<sub>3</sub> as well as their SA are summarized in Table 1.

Fig. 2 shows TPD profiles of CO<sub>2</sub> adsorbed on the REOs. Several desorption peaks of CO<sub>2</sub> from light REOs, such as La<sub>2</sub>O<sub>3</sub>, CeO<sub>2</sub>,

**Fig. 1.** XRD profiles of REO and Sc<sub>2-x</sub>Yb<sub>x</sub>O<sub>3</sub> samples calcined at 800 °C.
