Complication in strabismus surgery

Triamcinolone

Retinal artery embolization

Brown's syndrome

ABSTRACT

**Clinical case:** A 4-year-old patient, who presented with an immediate orbital hematoma as a result of a subtenon injection of triamcinolone in the trochlear region of the right eye on finishing a surgical procedure for Brown's syndrome. After one week, when it could be examined better, the presence of a cherry red spot was observed due to the embolization of the central artery of the retina by triamcinolone crystals.

**Discussion:** Triamcinolone is an anti-inflammatory drug currently used in ophthalmology for the treatment of various conditions. Although exceptional, it has been described that its use may provoke embolizations due to the entry of the steroid into the circulation.

**Grave complicación en el transcurso de una cirugía de estrabismo**

RESUMEN

Palabras clave:

Complicación en cirugía

de estrabismo

Triamcinolona

Embolización arterial retiniana

Síndrome de Brown

**Caso clínico:** Paciente de 4 años de edad, que como consecuencia de una inyección de triamcinolona subtenoniana en la región de la tróclea del ojo derecho al finalizar una cirugía para el síndrome de Brown presenta un hematoma orbital inmediato que al cabo de una semana, cuando se pudo explorar mejor, puso en evidencia la presencia de una mancha rojo-cereza secundaria a la embolización de la arteria central de la retina por cristales de triamcinolona.

**Discusión:** La triamcinolona es un antiinflamatorio de uso corriente en oftalmología para el tratamiento de afecciones variadas. Aunque excepcional, se ha descrito que su utilización puede provocar embolizaciones por entrada del esteroide en la circulación.

## Introduction

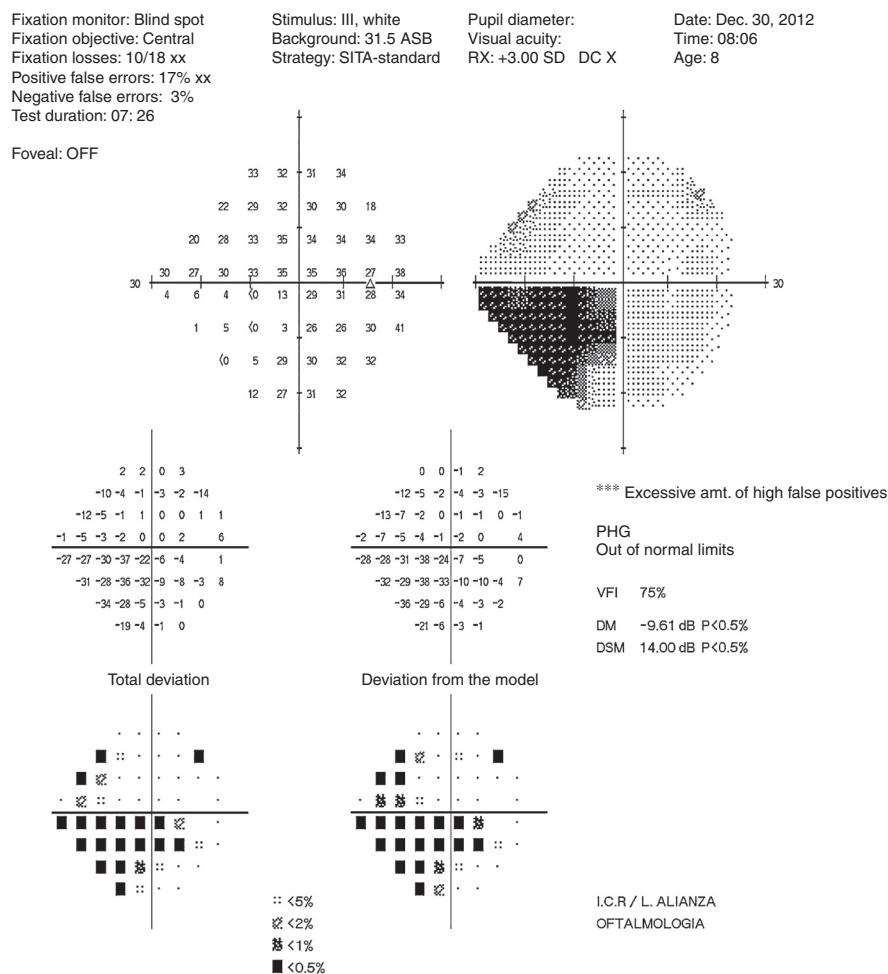

Strabismus surgery is not exempt of complications.<sup>1</sup> The literature describes a range of complications, from simple conjunctival cysts to muscular dislocation and the feared perforation or endophthalmitis.<sup>1,2</sup> However and despite the broad range of described complications, the authors did not find any as that described below.

## Clinic case report

A child, aged 4, brought to the practice by his parents who detected that he deviated his gaze since birth. Motor examination revealed orthophoria in primary position, downshoot in levoversion and difficulty for elevating in all positions, markedly in the field of action of the right lower oblique muscle (Fig. 1). Visual acuity of 20/20 in each eye with sphere of
