## ABSTRACT

We devise a generic framework where a weakest precondition semantics, in the form of indexed posets, is derived from a monad whose Kleisli category is enriched by posets. It is inspired by Jacobs' recent identification of a categorical structure that is common in various predicate transformers, but adds generality in the following aspects: (1) different notions of modality (such as “may” vs. “must”) are captured by Eilenberg–Moore algebras; (2) nested alternating branching—like in games and in probabilistic systems with nondeterministic environments—is modularly modeled by a monad on the Eilenberg–Moore category of another.

## 1. Introduction

Among various styles of program semantics, the one by *predicate transformers* [2] is arguably the most intuitive. Its presentation is inherently logical, representing a program's behaviors by what properties (or *predicates*) hold before and after its execution. Predicate transformer semantics therefore form a basis of *program verification*, where specifications are given in the form of pre- and post-conditions [3]. It has also been used for *refinement* of specifications into programs (see e.g. [4]). Its success has driven extensions of the original nondeterministic framework, e.g. to the probabilistic one [5,6] and to the setting with both nondeterministic and probabilistic branching [7].

*A categorical picture* More recently, Jacobs in his series of papers [8–10] has pushed forward a categorical view on predicate transformers. It starts with a monad  $T$  that models a notion of branching. Then a program—henceforth called a (*branching*) *computation*—is a Kleisli arrow  $X \rightarrow TY$ ; and the weakest precondition semantics is given as a contravariant functor  $\mathbb{P}^{\mathcal{K}\ell}: \mathcal{K}\ell(T)^{\text{op}} \rightarrow \mathbb{A}$ , from the Kleisli category to the category  $\mathbb{A}$  of suitable ordered algebras.

<sup>☆</sup> An earlier version of this paper [1] has been presented at the Twelfth International Workshop on Coalgebraic Methods in Computer Science (CMCS 2014), 5–6 April 2014, Grenoble, France.

For example, in the basic nondeterministic setting,  $T$  is the powerset monad  $\mathcal{P}$  on **Sets** and  $\mathbb{A}$  is the category  $\mathbf{CL}_\wedge$  of complete lattices and  $\wedge$ -preserving maps. The weakest precondition functor  $\mathbb{P}^{\mathcal{K}\ell}: \mathcal{K}\ell(T)^{\text{op}} \rightarrow \mathbf{CL}_\wedge$  then carries a function  $f: X \rightarrow \mathcal{P}Y$  to

$$\text{wpre}(f) : \mathcal{P}Y \longrightarrow \mathcal{P}X, \quad Q \longmapsto \{x \in X \mid f(x) \subseteq Q\}. \quad (1)$$

Moreover it can be seen that: 1) the functor  $\mathbb{P}^{\mathcal{K}\ell}$  factors through the comparison functor  $K: \mathcal{K}\ell(\mathcal{P}) \rightarrow \mathcal{E}\mathcal{M}(\mathcal{P})$  to the Eilenberg–Moore category  $\mathcal{E}\mathcal{M}(\mathcal{P})$ ; and 2) the extended functor  $\mathbb{P}^{\mathcal{E}\mathcal{M}}$  has a dual adjoint  $\mathbb{S}$ . The situation is as follows.

$$\begin{array}{ccc}
 & \mathbb{S} & \\
 \mathbf{CL}_\wedge & \xrightarrow{\quad} & (\mathbf{CL}_\vee)^{\text{op}} \cong \mathcal{E}\mathcal{M}(\mathcal{P})^{\text{op}} \\
 & \perp & \\
 & \mathbb{P}^{\mathcal{E}\mathcal{M}} & \\
 \mathbb{P}^{\mathcal{K}\ell} = \mathbb{P}^{\mathcal{E}\mathcal{M}} \circ K^{\text{op}} & \xleftarrow{\quad} & \mathcal{K}\ell(\mathcal{P})^{\text{op}} \xrightarrow{\quad} K^{\text{op}}
 \end{array} \quad (2)$$

Here the functor  $K$  carries  $f: X \rightarrow \mathcal{P}Y$  to  $f^\dagger: \mathcal{P}X \rightarrow \mathcal{P}Y, P \mapsto \bigcup_{x \in P} f(x)$ . We shall call this mapping  $f \mapsto f^\dagger$  a *superposed-state transformer semantics*—it can be understood as the *strongest postcondition semantics* in this specific instance of  $T = \mathcal{P}$ , but not necessarily in other instances. See [Remark 2.11](#).

Therefore the picture (2)—understood as the one below—identifies a general categorical structure that underlies predicate transformer semantics. The dual adjunction here (which is in fact an isomorphism in the specific instance of (2)) indicates a “duality” between (backward) predicate transformers and (forward) superposed-state transformers.

$$\begin{array}{ccc}
 \left( \begin{array}{c} \text{(backward) predicate} \\ \text{transformers} \end{array} \right) & \begin{array}{c} \xrightarrow{\quad \mathbb{S} \quad} \\ \xleftarrow{\quad \perp \quad} \end{array} & \left( \begin{array}{c} \text{(forward) superposed-state} \\ \text{transformers} \end{array} \right) \\
 \begin{array}{c} \text{weakest precondition} \\ \text{semantics,} \\ \text{predicate transformer} \\ \text{semantics} \end{array} & \begin{array}{c} \swarrow \\ \searrow \end{array} & \left( \begin{array}{c} \text{(branching)} \\ \text{computations} \end{array} \right) & \begin{array}{c} \swarrow \\ \searrow \end{array} & \begin{array}{c} \text{superposed-state} \\ \text{transformer semantics} \end{array}
 \end{array} \quad (3)$$

Jacobs has identified other instances of (3) for: discrete probabilistic branching [8]; quantum logic [8]; and continuous probabilistic branching [9].<sup>1</sup> See [10] for an overview and also for additional instances. In all these instances the notion of *effect module*—originally from the study of quantum probability [11]—plays an essential role as algebras of “quantitative logics.”

*Towards generic weakest precondition semantics* In [8–10] the picture (3) is presented through examples, and its categorical axiomatics—that encompass many different instances of the picture—have not been pursued as a main goal.<sup>2</sup> Finding such axiomatics is the current paper’s aim. In doing so, moreover, we acquire additional generality in two aspects: *different modalities* and *nested alternating branching*.

To motivate the first aspect of generality, observe that the weakest precondition semantics in (1) is the *must* semantics. The *may* variant looks as interesting; it would carry a postcondition  $Q \subseteq Y$  to  $\{x \in X \mid f(x) \cap Q \neq \emptyset\}$ . The difference between the two semantics is much like the one between the modal operators  $\square$  and  $\diamond$ .

On the second aspect, situations are abound in computer science where a computation involves two heterogeneous layers of branching. Typically these layers correspond to two distinct *players* with conflicting interests. Examples are *games*, a two-player version of automata which are essential tools in various topics including model-checking; and *probabilistic systems* where it is common to include nondeterministic branching too for modeling the environment’s choices. Further details will be discussed later in Section 4.

*Predicates and modalities from monads* In this paper we present two categorical setups that are inspired by [12–14]—specifically by their use of  $T1$  as a domain of *truth values* or *quantities*.

The first “one-player” setup is when we have only one layer of branching. Much like in [8–10] we start from a monad  $T$ . Assuming that  $T$  is *order-enriched*—in the sense that its Kleisli category  $\mathcal{K}\ell(T)$  is **Posets**-enriched—we observe that:

- a natural notion of *truth value* arises from an object  $T\Omega$  (where the object  $\Omega$  is typically the terminal one 1);
- and a modality (like “may” and “must”) corresponds to a choice of an Eilenberg–Moore algebra  $\tau: T(T\Omega) \rightarrow T\Omega$ .

The required data set  $(T, \Omega, \tau)$  shall be called a *predicate transformer situation*. We prove that it induces a *weakest precondition semantics* functor  $\mathcal{K}\ell(T)^{\text{op}} \rightarrow \mathbf{Posets}$ , and that it factors through  $K: \mathcal{K}\ell(T) \rightarrow \mathcal{E}\mathcal{M}(T)$ , much like in (2). The general setup addresses common instances like the original nondeterministic one [2] and the probabilistic predicate transformers

<sup>1</sup> Different terminologies are used in [8] to describe the picture (3). See [Remark 1.1](#).

<sup>2</sup> An exception is a unified treatment of branching weighted by a semiring  $R$ ; see e.g. [10, §3]. This, however, does not generalize to the probabilistic branching as it is.
