## Abstract

Comparative studies have been carried out on the leaf epidermal features of the species in the family Polygonaceae in West Africa. Epidermal cells are mainly isodiametric in *Symmeria paniculata*, irregular or more often polygonal with curved, straight and undulate to sinuate anticlinal walls. A few species e.g. *Polygonum plebeium*, *Oxygonum sinuatum*, *Persicaria nepalensis* and *Harpagocarpus snowdenii* have striations on their epidermal walls. All species except *Afrobrunnichia erecta* and *H. snowdenii* are amphistomatic and the family is characterized by a wide range of stomata types such as the anisocytic in *P. plebeium*, cyclocytic in *S. paniculata* and a few *Persicaria*, anomocytic, diacytic, parallelocytic and paracytic which is regarded as the basic type for the family based on its widest occurrence among the species. However, different stomata types may occur on the same leaf surface. The unicellular, or multicellular, uniseriate aggregated trichomes are significant in the recognition of taxa in the *Persicaria* except in *P. senegalensis forma albotomentosa* which has short uniseriate flagelliform trichomes. The significance of these observations is discussed in relation to the taxonomy of the family.

## 1. Introduction

Polygonaceae are a cosmopolitan family of herbs, shrubs, small trees or climbers characterized by simple leaves with sheathing ochreae stipules, unilocular ovary and endospermic seeds (Hutchinson and Dalziel, 1954; Brummitt, 1992). The family is generally considered to comprise 30 to 49 genera embracing about 750 species (Heywood, 1978; Brummitt, 1992). Most genera are restricted to the Northern temperate regions while others are tropical or subtropical (Heywood, 1978). Polygonaceae are poorly represented in West Africa, and Hutchinson and Dalziel (1954) recorded five genera and fifteen species for the West African sub-region. The genera include *Polygonum*, *Afrobrunnichia*, *Symmeria*, *Harpagocarpus* and *Rumex*. However, others such as *Oxygonum*, which is restricted to the northern part of Nigeria, and the widespread

*Antigonon*, have been collected and documented. The species occupy diverse ecological areas of the region ranging from lowland rainforests and highlands to savanna (Ayodele, 2003).

The classification of the Polygonaceae at and above the generic level has been unstable over the years. Until recently (Haraldson, 1978), the family was regarded as being made up of more than two subfamilies, with various authors differing in their circumscriptions of the subfamilies (Bentham and Hooker, 1880; Buchinger, 1957; Jaretsky, 1925; Takhtajan, 1980; Brandbyge, 1992). Haraldson (1978) recognised two subfamilies — the Polygonoideae based on *Polygonum* L. and the Eriogonoideae based on *Eriogonum* Mich. The tribal treatment of *Polygonum sensu lato* has itself been varied since the time of Linnaeus (1753) with several authors placing the segregate taxa contained into different tribes and subfamilies (Ronse Decraene and Akeroyd, 1988). However, Haraldson's (1978) proposed division of Polygonaceae and Persicarieae brought order into the taxonomy of this group. Other tribes include the Rumiceae, Triplareae and the Coccolebae.
