Skew polynomial rings

$q$ -skew derivation

Character skew derivation

## ABSTRACT

Following [17], a  $\sigma$ -derivation  $\delta$  is called *quasi-algebraic* if there exist  $a, a_i \in Q$  such that  $\delta^k(x) + \sum_{i=1}^{k-1} a_i \delta^i(x) + ax - \sigma^k(x)a = 0$  for  $x \in Q$ . Let  $k$  be the minimal such integer and  $g_0, g_1, \dots$  mutually outer automorphisms of  $Q$ . Let  $f(z_{ij})$  be a generalized polynomial in variables  $z_{ij}$ , where  $i \geq 0$  and  $0 \leq j < k$ . It is shown in [6] that if  $f(g_i \delta^j(x))$  or  $f(\delta^j g_i(x))$  is an identity, then so is  $f(z_{ij})$ . We generalize this to sets of skew derivations in Theorems 1 and 2. In Theorem 3, we apply these results to the Ore extensions of several variables of [2] and in Theorem 4 to the character Hopf algebras of the character skew derivations of [12].

1. Results

A map  $\theta : R \rightarrow R$  is called *additive* if  $\theta(x + y) = \theta(x) + \theta(y)$  for  $x, y \in R$ . The set of all additive maps  $R \rightarrow R$  forms a ring under point-wise addition and composition multiplication. By an automorphism of  $R$ , we mean a *bijective* additive map  $\sigma : R \rightarrow R$  such that  $\sigma(xy) = \sigma(x)\sigma(y)$  for  $x, y \in R$ . Given a unit  $u \in R$ , the map  $I_u : x \in R \mapsto uxu^{-1}$  defines an automorphism of  $R$ , called the inner automorphism defined by  $u$ . By a  $\sigma$ -derivation of  $R$ , where  $\sigma$  is an automorphism of  $R$ , we mean an additive map  $\delta : R \rightarrow R$  such that

$$\delta(xy) = \delta(x)y + \sigma(x)\delta(y) \quad \text{for } x, y \in R.$$

We call  $\sigma$  the associated automorphism of  $\delta$ . For brevity, we also call  $\delta$  a *skew* derivation by suppressing  $\sigma$ . Given  $a \in R$ , the map  $\text{ad}_\sigma(a) : x \in R \mapsto ax - \sigma(x)a$  defines a  $\sigma$ -derivation of  $R$ , called the inner  $\sigma$ -derivation defined by  $a$ . By a differential polynomial  $\varphi$ , we mean a generalized polynomial with its variables acted by composition products of automorphisms and skew derivations of  $R$ . (See [8–11].) We call  $\varphi$  *linear* in the variable  $x$  if  $\varphi = \sum_i A_i \mu_i(x) B_i$ , where  $A_i, B_i$  are differential polynomials containing no  $x$  and where  $\mu_i$  are composition products of automorphisms and skew derivations of  $R$ . We call  $\varphi$  *multi-linear* if it is linear in all the variables it contains. We call  $\varphi$  *linear* if it contains only one variable and is linear in this variable. If a differential polynomial  $\varphi$  vanishes for any evaluations of its variables in  $R$ , then we call  $\varphi$  a differential *identity* of  $R$ . An identity  $\varphi$  is called linear or multi-linear respectively if the differential polynomial  $\varphi$  is linear or multi-linear respectively. Our aim here is to investigate these identities. Let  $Q$  denote the left Martindale quotient ring of  $R$ . (See [1,18] for a definition.) As shown in [7–11], we have to work in  $Q$  as follows: Let  $I \trianglelefteq R$  denote that  $I$  is a two-sided ideal of  $Q$ . For each  $a \in Q$ , the family  $\{a + I : 0 \neq I \trianglelefteq R\}$  forms a neighborhood system of  $Q$  at the point  $a$  by the primeness of  $R$ . These neighborhood systems define a topology, called the *ideal* topology of  $Q$ . Clearly, an additive map  $\theta : Q \rightarrow Q$  is continuous if and only if for any two-sided ideal  $0 \neq I \trianglelefteq R$  there exists a two-sided ideal  $0 \neq J \trianglelefteq R$  such that  $\theta(J) \subseteq I$ . An automorphism  $\sigma$  of  $Q$  is called *bi-continuous* if both  $\sigma$  and  $\sigma^{-1}$  are continuous. A skew derivation is called continuous if it is continuous and its associated automorphism is bi-continuous. Any automorphism of  $R$  can be extended uniquely to a bi-continuous automorphism of  $Q$ . Analogously, any skew derivation of  $R$ , together with its associated automorphism, can be extended uniquely to a continuous skew derivation of  $Q$ . So any differential polynomial of  $R$  extends to a unique differential polynomial of  $Q$ . By [22], any linear differential identity of  $R$  extends to a linear differential identity of  $Q$  in this way. It thus suffices to investigate linear differential identities of  $Q$  involving bi-continuous automorphisms and continuous skew derivations. So we set

$\mathbb{A} :=$  the set of bi-continuous automorphisms of  $Q$ ,

$\mathbb{L}_\sigma :=$  the set of continuous  $\sigma$ -derivations of  $Q$  for each  $\sigma \in \mathbb{A}$  and
