ABSTRACT

A vertex-edge dominating set of a graph *G* is a set *D* of vertices of *G* such that every edge of *G* is incident with a vertex of *D* or a vertex adjacent to a vertex of *D*. The vertex-edge domination number of a graph *G*, denoted by $\gamma_{ve}(T)$, is the minimum cardinality of a vertex-edge dominating set of *G*. We prove that for every tree *T* of order $n \ge 3$ with *l* leaves and *s* support vertices, we have $(n - l - s + 3)/4 \le \gamma_{ve}(T) \le n/3$, and we characterize the trees attaining each of the bounds.

RÉSUMÉ

Un ensemble sommet–arête dominant d'un graphe *G* est un ensemble *D* de sommets de *G* tel que chaque arête de *G* soit incidente à un sommet de *D* ou à un sommet adjacent à un sommet de *D*. Le nombre de domination sommet–arête d'un graphe *G*, noté $\gamma_{ve}(T)$, est le cardinal minimum d'un ensemble sommet–arête dominant de *G*. Nous prouvons que, pour chaque arbre *T* d'ordre $n \ge 3$ avec *l* feuilles et des sommets *s* de soutien, que nous avons $(n - l - s + 3)/4 \le \gamma_{ve}(T) \le n/3$, et nous caractérisons les arbres atteignant chacune des limites.

1. Introduction

Let G = (V, E) be a graph. By the neighborhood of a vertex v of G we mean the set $N_G(v) = \{u \in V(G): uv \in E(G)\}$. The degree of a vertex v, denoted by $d_G(v)$, is the cardinality of its neighborhood. By a leaf we mean a vertex of degree one, while a support vertex is a vertex adjacent to a leaf. We say that a support vertex is strong (weak, respectively) if it is adjacent to at least two leaves (exactly one leaf, respectively). We denote by P_n the path on n vertices. Let T be a tree, and let v be a vertex of T. We say that v is adjacent to a path P_n if there is a neighbor of v, say x, such that the subtree

resulting from T by removing the edge vx and which contains the vertex x as a leaf, is a path P_n . By a star we mean a connected graph in which exactly one vertex has degree greater than one.

A subset $D \subseteq V(G)$ is a dominating set of G if every vertex of $V(G) \setminus D$ has a neighbor in D. The domination number of G is the minimum cardinality of a dominating set of G. For a comprehensive survey of domination in graphs, see [2,3].

An edge $e \in E(G)$ is vertex-edge dominated by a vertex $v \in V(G)$ if e is incident to v, or e is adjacent to an edge incident to v. A subset $D \subseteq V(G)$ is a vertex-edge dominating set, abbreviated VEDS, of G if every edge of G is vertex-edge dominated by a vertex of D. The vertex-edge domination number of G, denoted by $\gamma_{ve}(G)$, is the minimum cardinality of a vertex-edge dominating set of G. A vertex-edge dominating set of G of minimum cardinality is called a $\gamma_{ve}(G)$ -set. Vertex-edge domination in graphs was introduced in [7], and further studied in [6].

Chellali and Haynes [1] established the following lower bound on the total domination number of a tree. For every tree *T* of order *n* with *l* leaves, we have $\gamma_t(T) \ge (n - l + 2)/2$. They also characterized the extremal trees. In [4] a lower bound on the total outer-independent domination number of a tree was given together with the characterization of the extremal trees. Lemańska [5] proved that the domination number of a tree is bounded below by (n - l + 2)/3.

We prove the following bounds on the vertex–edge domination number of a tree *T* of order $n \ge 3$ with *l* leaves and *s* support vertices, $(n - l - s + 3)/4 \le \gamma_{ve}(T) \le n/3$. We also characterize the trees attaining each of the bounds.

2. Results

We begin with the following straightforward observation.

Observation 1. For every connected graph G of diameter at least two, there exists a $\gamma_{ve}(G)$ -set that contains no leaf.

First we show that if *T* is a nontrivial tree of order *n* with *l* leaves and *s* support vertices, then $\gamma_{ve}(T)$ is bounded below by (n - l - s + 3)/4. For the purpose of characterizing the trees attaining this bound, we introduce a family \mathcal{T} of trees $T = T_k$ that can be obtained as follows. Let T_1 be a path P_5 . If *k* is a positive integer, then T_{k+1} can be obtained recursively from T_k by one of the following operations.

- Operation \mathcal{O}_1 : Attach a vertex by joining it to any support vertex of T_k .
- Operation \mathcal{O}_2 : Attach a path P_2 by joining one of its vertices to a vertex of T_k , which is not a leaf and is adjacent to a support vertex of degree two.
- Operation \mathcal{O}_3 : Attach a path P_4 by joining one of its leaves to a leaf of T_k adjacent to a weak support vertex.

We now prove that for every tree *T* of the family \mathcal{T} we have $\gamma_{ve}(T) = (n - l - s + 3)/4$.

Lemma 2. If $T \in T$, then $\gamma_{ve}(T) = (n - l - s + 3)/4$.

Proof. We use the induction on the number *k* of operations performed to construct the tree *T*. If $T = T_1 = P_5$, then $(n - l - s + 3)/4 = (5 - 2 - 2 + 3)/4 = 1 = \gamma_{ve}(T)$. Let *k* be a positive integer. Assume that the result is true for every tree $T' = T_k$ of the family \mathcal{T} constructed by k - 1 operations. Let *n'* be the order of the tree *T'*, *l'* the number of its leaves, and *s'* the number of support vertices. Let $T = T_{k+1}$ be a tree of the family \mathcal{T} constructed by *k* operations.

First assume that *T* is obtained from *T'* by operation \mathcal{O}_1 . We have n = n' + 1, l = l' + 1 and s = s'. It is straightforward to see that any $\gamma_{ve}(T')$ -set is a VEDS of the tree *T*. Thus $\gamma_{ve}(T) \leq \gamma_{ve}(T')$. Obviously, $\gamma_{ve}(T') \leq \gamma_{ve}(T)$. This implies that $\gamma_{ve}(T) = \gamma_{ve}(T')$. We now get $\gamma_{ve}(T) = \gamma_{ve}(T') = (n' - l' - s' + 3)/4 = (n - 1 - l + 1 - s + 3)/4 = (n - l - s + 3)/4$.

Now assume that *T* is obtained from *T'* by operation \mathcal{O}_2 . We have n = n'+2, l = l'+1 and s = s'+1. It is straightforward to see that any $\gamma_{ve}(T')$ -set is a VEDS of the tree *T*. Thus $\gamma_{ve}(T) \leq \gamma_{ve}(T')$. This implies that $\gamma_{ve}(T) = \gamma_{ve}(T')$. We now get $\gamma_{ve}(T) = \gamma_{ve}(T') = (n'-l'-s'+3)/4 = (n-2-l+1-s+1+3)/4 = (n-l-s+3)/4$.

Now assume that *T* is obtained from *T'* by operation \mathcal{O}_3 . We have n = n' + 4, l = l' and s = s'. We denote by *x* the leaf to which P_4 is attached. Let $v_1v_2v_3v_4$ be the attached path. Let v_1 be joined to *x*. Let *D'* be any $\gamma_{ve}(T')$ -set. It is easy to see that $D' \cup \{v_2\}$ is a VEDS of the tree *T*. Thus $\gamma_{ve}(T) \leq \gamma_{ve}(T') + 1$. Now let us observe that there exists a $\gamma_{ve}(T)$ -set that does not contain the vertices v_4 , v_3 , and v_1 . Let *D* be such a set. To dominate the edge v_3v_4 , we have $v_2 \in D$. Observe that $D \setminus \{v_2\}$ is a VEDS of the tree *T'*. Therefore $\gamma_{ve}(T') \leq \gamma_{ve}(T) - 1$. We now conclude that $\gamma_{ve}(T) = \gamma_{ve}(T') + 1$. We get $\gamma_{ve}(T) = \gamma_{ve}(T') + 1 = (n' - l' - s' + 3)/4 + 1 = (n - 4 - l - s + 7)/4 = (n - l - s + 3)/4$. \Box

We now give a lower bound on the vertex-edge domination number of a tree together with the characterization of the extremal trees.

Theorem 3. If *T* is a nontrivial tree of order *n* with *l* leaves and *s* support vertices, then $\gamma_{ve}(T) \ge (n - l - s + 3)/4$ with equality if and only if $T \in \mathcal{T}$.

Proof. If diam(*T*) = 1, then *T* = *P*₂. We have $(n - l - s + 3)/4 = (2 - 2 - 2 + 3)/4 < 1 = \gamma_{ve}(T)$. If diam(*T*) = 2, then *T* is a star. We have l = n - 1 and s = 1. Consequently, $(n - l - s + 3)/4 = (n - n + 1 - 1 + 3)/4 = 3/4 < 1 = \gamma_{ve}(T)$.
