Hydroxyl radicals

Iopromide removal

### ABSTRACT

Graphene-based materials, including graphene oxide (GO), reduced-graphene oxide (rGO), and non-oxidative graphene (nOG) were evaluated for catalytic ozonation in water solutions. Among the graphene-based materials evaluated for catalytic ozonation, it was confirmed that rGO was unsuitable to apply to the ozone (O<sub>3</sub>)/graphene-based materials catalytic process because the high electron mobility of rGO prevented the transformation of O<sub>3</sub> into hydroxyl radicals (\*OH). On the other hand, GO, which had sufficient oxygenated functional groups on the surface, decomposed and generated the most amount of O<sub>3</sub> and \*OH, respectively. Although O<sub>3</sub>/nOG process produced a lower amount of \*OH than O<sub>3</sub>/GO process, nOG was more effective than GO for the transformation yields of O<sub>3</sub> into \*OH. Furthermore, nOG could generate \*OH not only in the bulk phase, but also on the surface of nOG during catalytic ozonation. However, iopromide (IPM) was effectively removed during O<sub>3</sub>/GO process due to the more \*OH generated in the bulk phase than O<sub>3</sub>/nOG process.

### 1. Introduction

Graphene is rapidly becoming a popular material for use in materials science and could potentially have a significant impact on related, real-world applications [1,2]. Since this strictly two-dimensional monolayer of sp<sup>2</sup> carbon atoms exhibits remarkable mechanical, thermal, optical and electrical properties [3–6], graphene has emerged as a promising material for applications in various fields [7–11]. However, graphene is difficult to produce in large quantities to obtain such theoretical uses. Thus, graphene-based flake materials, such as graphene oxide (GO), reduced-graphene oxide (rGO), and non-oxidative graphene (nOG), have been widely applied because GO, which constitutes an oxygenating functional group, is easy to functionalize [12], rGO can recover sp<sup>2</sup> structures and physical properties [13], and nOG can be easily mass produced.

Graphene-based materials have also been used in environmental applications for water purification, such as adsorption of contaminants [14–16], membrane technology [17,18], and catalytic processes [19–21]. In particular, nano-carbon materials can be applied to chemical catalytic oxidation processes, such as catalytic ozonation. Ozone (O<sub>3</sub>) is a strong oxidant capable of reacting with a wide range of organic and inorganic solutes in water. However, the direct reaction of O<sub>3</sub> is quite selective in organic oxidation because O<sub>3</sub> has a very low reactivity toward single-bond compounds and aromatic substitutes in the electron-withdrawing group [22]. Advanced oxidation processes (AOPs) involving the generation of hydroxyl radicals (\*OH), which are the most powerful oxidants that non-selectively react with many organic species, have received much attention for overcoming the limitations of ozonation [23]. With regard to the AOPs, O<sub>3</sub> has been applied to catalytic ozonation using nano-particles or carbon materials, because it can accelerate the initiation of the chain reaction that transforms O<sub>3</sub> into \*OH as a catalyst [24–26].

There have been several investigations of heterogeneous catalyses in ozonation using carbon-based materials, such as granular activated carbon (GAC) [27–30] and carbon nanotubes (CNTs)

Decomposition of (a) O<sub>3</sub> and (b) pCBA by O<sub>3</sub> alone and by the O<sub>3</sub>/graphene-based materials catalytic process using different materials, including GO, rGO, and nOG ([O<sub>3</sub>]<sub>0</sub> = 1 mg/L, [pCBA]<sub>0</sub> = 0.5 μM, materials concentration = 25 mg/L, pH 5). (c) The adsorption of pCBA by GO, rGO, and nOG ([pCBA]<sub>0</sub> = 0.5 μM, materials concentration = 25 mg/L, pH 5).

Table 1

$R_{ct}$  values and  $\cdot OH$  yields of the O<sub>3</sub>/graphene-based materials processes ([O<sub>3</sub>]<sub>0</sub> = 1 mg/L, [pCBA]<sub>0</sub> = 0.5 μM, nOG and GO concentration = 0, 25, 50, 100 mg/L, pH 5).

Parameters	O <sub>3</sub> alone		25 mg/L		50 mg/L		100 mg/L	
	$R_{ct}$	$\cdot OH$ yield	$R_{ct}$	$\cdot OH$ yield	$R_{ct}$	$\cdot OH$ yield	$R_{ct}$	$\cdot OH$ yield
nOG	$9.7 \times 10^{-9}$	$6.7 \times 10^{-8}$	$4.8 \times 10^{-8}$	$8.3 \times 10^{-8}$	$8.3 \times 10^{-8}$	$6.6 \times 10^{-8}$	$5.4 \times 10^{-7}$	$5.5 \times 10^{-8}$
GO	$1.1 \times 10^{-8}$	$7.1 \times 10^{-8}$	$1.2 \times 10^{-6}$	$6.7 \times 10^{-8}$	$2.1 \times 10^{-6}$	$6.7 \times 10^{-8}$	$8.4 \times 10^{-6}$	$6.8 \times 10^{-8}$

[31–33]. Although graphene-based materials have been used as catalysts in catalytic ozonation, Li et al. [34] and Wang et al. [35] reported the removal of bisphenol A and 4-nitrophenol respectively using rGO modified with metal oxide (MnO<sub>2</sub>), which is generally well known as a catalyst [36,37], and Rocha et al. [38] used metal-free and nitrogen-doped graphene-based materials.

Currently, there have been no comparative evaluations completed of catalytic ozonation using different virgin graphene-based materials. To understand the catalytic effect of the graphene-based materials accurately, it is needed to investigate the pure materials without further doping or modification. Additionally, the
