## **Highlights**

- Field measurements of thermal stratification in two large industrial warehouses were conducted
- Multiple Reference Frame model was validated for modeling ceiling rotating fan for thermal destratification
- Pressure Jump model was applied to modeling axial bucket fan for thermal destratification
- A dimensionless non-uniformity coefficient of temperature was used for evaluating destratification performance
- Different thermal destratification strategies were compared for the energy savings of the warehouses

## **Abstract**

Thermal stratification in large warehouses is a common phenomenon in winter, especially for cold climates. Buoyancy-driven warm air tends to move upwards towards ceilings creating vertical temperature gradients with upper higher temperatures, and consequently leading to excessive heat losses through roofs. These warehouses therefore require thermal destratification through certain air mixing strategies, the selection of which often relies on engineering rules of thumb and experiences but can be better determined through combined experimental and numerical approaches. This paper investigated different thermal destratification methods in two industrial warehouses based on field measurements and CFD simulations with the focus on the quantification of thermal stratification, and the suitable methods modeling air mixing devices, e.g. ceiling rotating fans and bucket fans. The numerical models were first validated by field measurements and then
