Twisted cubes

## ABSTRACT

A long-standing conjecture mentions that a  $k$ -connected graph  $G$  admits  $k$  independent spanning trees (ISTs for short) rooted at an arbitrary node of  $G$ . An  $n$ -dimensional twisted cube, denoted by  $TQ_n$ , is a variation of hypercube with connectivity  $n$  and has many features superior to those of hypercube. Yang (2010) first proposed an algorithm to construct  $n$  edge-disjoint spanning trees in  $TQ_n$  for any odd integer  $n \geq 3$  and showed that half of them are ISTs. At a later stage, Wang et al. (2012) inferred that the above conjecture in affirmative for  $TQ_n$  by providing an  $\mathcal{O}(N \log N)$  time algorithm to construct  $n$  ISTs, where  $N = 2^n$  is the number of nodes in  $TQ_n$ . However, this algorithm is executed in a recursive fashion and thus is hard to be parallelized. In this paper, we revisit the problem of constructing ISTs in twisted cubes and present a non-recursive algorithm. Our approach can be fully parallelized to make the use of all nodes of  $TQ_n$  as processors for computation in such a way that each node can determine its parent in all spanning trees directly by referring its address and tree indices in  $\mathcal{O}(\log N)$  time.

## 1. Introduction

Let  $V(G)$  and  $E(G)$  denote the node set and edge set of a graph  $G$ , respectively. A set of spanning trees in  $G$  is called *independent spanning trees* (ISTs for short) if all the trees are rooted at the same node  $r$  such that, for any other node  $v \in V(G) \setminus \{r\}$ , the paths from  $v$  to  $r$  in any two trees are internally node-disjoint (i.e., there exists no common node in the two paths except  $v$  and  $r$ ). Constructing multiple spanning trees in a graph has been studied not only from a theoretical point of view but also from some practical applications. In particular, the construction of ISTs is important due to the applications to fault-tolerant broadcasting and secure message distribution in reliable interconnection networks [2,13,18,22]. Suppose that we have  $k$  ISTs rooted at a node  $r$  in a network. For the former, the fault-tolerant broadcasting can be achieved by sending  $k$  copies of a message along  $k$  ISTs on the network provided that there are at most  $k - 1$  faulty nodes (different from  $r$ ) and/or faulty edges in the network. For the latter, if a message at the source node is separated into  $k$  different parts, by sending the  $k$  parts along  $k$  ISTs on the network, then the message is secure in the message distributing.

Let  $G - F$  stand for the graph obtained from  $G$  by removing a subset  $F \subset V(G)$ . A graph  $G$  is  $k$ -connected if  $|V(G)| > k$  and  $G - F$  is connected for any subset  $F \subset V(G)$  with  $|F| < k$ . Zehavi and Itai [29] proposed the following conjecture: if  $G$  is a  $k$ -connected graph, then it admits  $k$  ISTs rooted at an arbitrary node. Till now, the conjecture has been affirmed only for  $k \leq 4$  (see [13,6,29,7] for  $k = 2, 3, 4$ , respectively) and is still open for  $k \geq 5$ . Also, research of this topic for applications has been focused on some interconnection networks (see [4,5,12,18,19,22–24,26,28,27] and quotes therein).

Hilbers et al. [11] first introduced the family of twisted cubes as a variation of hypercubes in order to achieving some improvements of structure properties in contrast to hypercubes. Let  $TQ_n$  denote the  $n$ -dimensional twisted cube. Chang et al. [3] showed that  $TQ_n$  is an  $n$ -connected graph with the diameter, wide diameter, and faulty diameter being about half of those in comparable hypercube. Although Abraham and Padmanabhan [1] pointed out the asymmetry of twisted cubes, this does not diminish an upsurge of research on twisted cubes. A lot of research results on  $TQ_n$  can be found in the literature [8–10,16,14,15,17,19,21,25,20]. In particular, Yang [21] proposed an algorithm to construct  $n$  edge-disjoint spanning trees in  $TQ_n$  for any odd integer  $n \geq 3$  and showed that half of them are ISTs. Wang et al. [19] further proposed an algorithm for constructing  $n$  ISTs with an arbitrary node as the root in  $\mathcal{O}(N \log N)$  time, where  $N = 2^n$  is the number of nodes in  $TQ_n$ . However, this algorithm is executed in a recursive fashion and thus is hard to be parallelized.

In this paper, we revisit the problem of constructing ISTs in twisted cubes. An algorithm developed for an interconnection network is said to be *fully parallelized* if it could make the use of all nodes of such a network as processors for computation. An obvious advantage of a fully parallelized algorithm is that it can lead to a better utilization of computing resources. Accordingly, we present a non-recursive and fully parallelized algorithm for constructing  $n$  ISTs rooted at an arbitrary node in  $TQ_n$ . A crucial practice of our algorithm is to find the parent of every node in each spanning tree directly, and consequently the algorithm can be parallelized to run in  $\mathcal{O}(\log N)$  time using  $N = 2^n$  nodes of  $TQ_n$  as processors. Note that the computation of each node only relies on the information of its address and tree indices. The algorithm is efficient because there are  $n$  ISTs to be constructed and each IST contains  $2^n$  nodes.

The rest of this paper is organized as follows. Section 2 formally gives the definition of twisted cubes and some useful terminologies and notations. Section 3 presents our algorithm for constructing  $n$  ISTs in  $TQ_n$  and provides examples as illustration. Section 4 proves the correctness of the algorithm and analyzes its complexity. The final section contains our concluding remarks.

2. Preliminary

Let  $\mathbb{Z}_n = \{0, 1, \dots, n - 1\}$ . For a binary string  $x = x_{n-1}x_{n-2} \dots x_0$  and an integer  $i \in \mathbb{Z}_n$ , we define  $\overset{\dots}{\oplus}(x, i) = x_i \oplus x_{i-1} \oplus \dots \oplus x_0$ , where  $\oplus$  is the bit exclusive-OR operation. The  $n$ -dimensional twisted cube, denoted by  $TQ_n$ , is a variant of the  $n$ -dimensional hypercube with  $2^n$  nodes, where each node is labeled by a unique binary string of length  $n$  as its address.  $TQ_n$  can be recursively defined as follows.

**Definition 1** ([11]). The 1-dimensional twisted cube  $TQ_1$  is the complete graph with two nodes labeled by 0 and 1. For an odd integer  $n \geq 3$ ,  $TQ_n$  consists of four subcubes  $TQ_{n-2}^{00}$ ,  $TQ_{n-2}^{01}$ ,  $TQ_{n-2}^{10}$ , and  $TQ_{n-2}^{11}$ , where  $TQ_{n-2}^{ab}$  for  $a, b \in \mathbb{Z}_2$  is isomorphic to  $TQ_{n-2}$  such that  $V(TQ_{n-2}^{ab}) = \{abx : x \in V(TQ_{n-2})\}$  (i.e., adding two preceding bits  $a$  and  $b$  in the front of a node labeled by  $x$ ) and  $E(TQ_{n-2}^{ab}) = \{(abx, aby) : (x, y) \in E(TQ_{n-2})\}$ . That is,  $V(TQ_n) = \cup_{ab \in \mathbb{Z}_2} V(TQ_{n-2}^{ab})$ . Define  $E(TQ_n) = \cup_{ab \in \mathbb{Z}_2} E(TQ_{n-2}^{ab}) \cup E'$ , where an edge  $(u, v) \in E'$  if and only if the two nodes  $u = u_{n-1}u_{n-2} \dots u_0$  and  $v = v_{n-1}v_{n-2} \dots v_0$  satisfy one of the following conditions:

- (1)  $u = \bar{v}_{n-1}v_{n-2} \dots v_0$ ;
- (2)  $u = \bar{v}_{n-1}\bar{v}_{n-2}v_{n-3} \dots v_0$  for  $\overset{\dots}{\oplus}(u, n - 3) = 0$ ;
- (3)  $u = v_{n-1}\bar{v}_{n-2}v_{n-3} \dots v_0$  for  $\overset{\dots}{\oplus}(u, n - 3) = 1$ .

Note that Definition 1 can only be applied for odd integer  $n$ . Fig. 1 depicts twisted cubes  $TQ_3$  and  $TQ_5$ , respectively. Recently, Wang et al. [19] showed that Definition 1 can be further extended to any integer  $n \geq 1$  by considering two types of  $TQ_n$  for even integer  $n$  as follows:

**Definition 2** ([19]). For an even integer  $n \geq 2$ , the  $n$ -dimensional twisted cube  $TQ_n$  is divided into two types: 0-type  $TQ_n$  and 1-type  $TQ_n$ , where the former is denoted by  $TQ_n^0$  and the latter is denoted by  $TQ_n^1$ . For  $b \in \mathbb{Z}_2$ ,  $V(TQ_n^b) = \{ibx : i \in \mathbb{Z}_2 \text{ and } x \in V(TQ_{n-1})\}$  and  $E(TQ_n^b) = \cup_{i \in \mathbb{Z}_2} \{(ibx, iby) : (x, y) \in E(TQ_{n-1})\} \cup E'$ , where an edge  $(u, v) \in E'$  if and only if the two nodes  $u = u_nb u_{n-2} \dots u_0$  and  $v = v_nb v_{n-2} \dots v_0$  satisfy  $u = \bar{v}_nb v_{n-2} \dots v_0$ .

Fig. 2 illustrates the two types of twisted cubes  $TQ_4^0$  and  $TQ_4^1$ , respectively. In the rest of this paper, we say  $TQ_n$  to mean either 0-type  $TQ_n$  or 1-type  $TQ_n$  if  $n$  is even and there is no ambiguity. Also, for notational convenience, a node  $x \in V(TQ_n)$  is denoted by  $x = (x_n)x_{n-1}x_{n-2} \dots x_0$ , where the first bit  $x_n$  enclosed by a pair of round brackets indicates that we can omit it if  $n$  is odd. According to Definitions 1 and 2, twisted cubes can be equivalently defined by the following non-recursive fashion.

**Theorem 1.** Let  $n \geq 1$  and  $v \in V(TQ_n)$ . For  $i \in \mathbb{Z}_n$ , the  $i$ th dimensional adjacent node (or the  $i$ -neighbor) of  $v$  in  $TQ_n$ , denoted by  $N_i(v)$  is computed as follows:
