This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

In this paper, we investigate theoretical aspects of the *Distributed Newest Vertex Bisection*. The paper contains the following highlights:

- We prove bounds on the number of global communications needed we executing the Distributed Newest Vertex Bisection, a variant of parallel conforming mesh adaptation.
- If the grid fulfills a compatibility condition that is described in the paper, the number of iterations of the Distributed Newest Vertex Bisection can be computed a priori, and therefore, no global communication is needed at all.
- A communication hiding exchange mechanism for the exchange of refinement flags during the refinement algorithm is presented.
- Numerical examples show that the proven bounds are sharp.
- Strong scaling for the parallel-adaptive algorithm on a peta scale super computer is presented.
- The discussed algorithms are implemented in the open-source software DUNE-ALUGrid (<https://gitlab.dune-project.org/extensions/dune-alugrid>) which is a module of the open-source software framework DUNE (www.dune-project.org) and for public download.
