### **Abstract**

Real Time Location Systems (RTLs) are critical components of many mobile robots that rely on them to safely operate in different environments, and their cyber-security is a growing concern. The goal of this paper is to demonstrate that there are statistically meaningful differences in the data provided by beacon-based RTLs between the case when there is an attacker or none, which can be used to detect attacks. A procedure to choose the more discriminant distribution of beacons is presented, as well as its empirical validation, based on data provided by a commercial RTL used by a mobile robot for indoor navigation. In the evaluation, three basic alternatives to define the distribution of beacons were considered to see which one was more discriminant, that is, the one with more differences. Statistical differences in the data gathered by the mobile robot, when the localization system is under attack, and when it is not, have been found. It has been also verified that these differences are larger or smaller depending on the location of the beacons.

*Keywords:* Cybersecurity, Indoor Positioning, Robotics, Cyber-attack, Beacon,  
Statistical-testing
