ABSTRACT

Electricity demand forecasting, as a vital tool in the electricity market, plays a critical role in power utilities, which can not only reduce production costs but also save energy resources, thus making the forecasting techniques become an indispensable part of the energy system. A novel combined forecasting method based on Back Propagation (BP) neural network, Adaptive Network-based Fuzzy Inference System (ANFIS) and Difference Seasonal Autoregressive Integrated Moving Average (diff-SARIMA) are presented in this paper. Firstly, the combined method uses all the three methods (BP, ANFIS, diff-SARIMA) to forecast respectively, and the three forecasting results were obtained. By multiplying optimal weight coefficients of the three forecasting results respectively and then adding them up, in the end the final forecasting results can be obtained. Among the three individual methods, BP and ANFIS had the ability to deal with the nonlinearity data, and diff-SARIMA had the ability to deal with the linearity and seasonality data. So the combined method eliminates drawbacks and incorporates in the merits of the individual methods. It has the capability to deal with the linearity, nonlinearity and seasonality data. In order to optimize weight coefficients, Differential Evolution (DE) optimization algorithm is brought into the combined method. To prove the superiority and accuracy, the capability of the combined method is verified by comparing it with the three individual methods. The forecasting results of the combined method proved to be better than all the three individual methods and the combined method was able to reduce errors and improve the accuracy between the actual values and forecasted values effectively. Using the half-hour electricity power data of the State of New South Wales in Australia, relevant experimental case studies showed that the proposed combined method performed better than the other three individual methods and had a higher accuracy.

35 **1. Introduction**

36 As people’s living standard and social-economic level have
 37 improved significantly, natural energy consumption continues to
 38 grow. Energy shortage becomes increasingly serious, so that more
 39 and more countries have attached great significance to these hot
 40 issues. As the major impetus to improve the development of soci-
 41 ety, electricity, one of the most important energy resources, plays
 42 a crucial role in the power system. It is known that, electricity is a
 43 resource which is difficult to store; besides, the electric system is
 44 affected by various unstable factors, namely weather, population,
 45 holidays, emergency and more. All the enormous problems make
 46 it difficult for the electricity production industry to estimate their
 47 output. Thus, an accurate and precise forecasting method is needed
 48 in the electricity market. On the contrary, inappropriate electricity
 49 demand forecasting will be counterproductive. An overestimated
 50 method will increase the workload of the electricity production
 51 and dissipate the energy resources. Bunn and Farmer pointed out
 52 that 10 million dollars of extra costs will increase in operating
 53 because of the 1% increasing forecasting errors in electricity pro-
 54 duction [1]. Meanwhile an underestimated method will paralyze
 55 the electricity grid, and some regions will face power failure sit-
 56 uations. It’s quite clear that a good forecasting method which can
 57 avoid many disasters is the key to respond to the future electric-
 58 ity demand. Therefore, precise electricity demand forecasting is the
 59 prerequisite to meet the demand, no matter whether for developed
 60 countries or developing countries. No matter for what kind of elec-
 61 tricity demand forecasts, long-term, midterm or others, developing
 62 a novel method which cannot only be effective but also improve the
 63 forecasting accuracy is a must [2].

64 More and more novel methods have been proposed in recent
 65 years because of the necessity for better forecasting performance.
 66 For example regression based methods and time series based meth-
 67 ods. Among the regression methods, linear regression methods are
 68 the most widely used ones. Goia et al. [3] applied linear regression
 69 method to forecast the peak load. Bianco et al. [4,5] used the linear
 70 regression models to forecast the electricity consumption in Italy.
 71 ARIMA is the most commonly used method in time series mod-
 72 els. For instance, Dong et al. [6] employed the time series approach
 73 to forecast long-term load, Erdogdu et al. [7] analyzed electrical
 74 demand by using ARIMA in Turkey, and Wang et al. [8] proposed
 75 seasonal ARIMA to forecast electricity demand in China. Because
 76 of the nonlinear characteristics which the electricity demand time
 77 series apparently experiences, even though these methods (regres-
 78 sion based methods, time series based methods) are presently
 79 mature, they still have drawbacks so that they cannot properly fore-
 80 cast the nonlinear load series. Moreover, these methods are affected
 81 by reliability and availability of external factors to a great extent.

82 For the last several decades, Artificial Intelligence (AI) methods
 83 have demonstrated the formidable ability in dealing with the sea-
 84 sonal and nonlinear load data. More and more new methodologies
 85 and techniques have emerged, such as the fuzzy logic system [9,10],
 86 the expert system [11,12], the grey prediction models [13,14]
 87 the Artificial Neural Networks (ANN) [15-17], the fuzzy inference

88 system [18-20]. Among all these methods, artificial neural
 89 networks and fuzzy theories are well received. Due to that they
 90 have the capacity to process the nonlinear data. Xiao et al. [21]
 91 developed a BP neural network with a rough set to forecast the
 92 short-term time series data, and the results proved the priority that
 93 BP had. Azwadi et al. [22] used the ANFIS to predict the temperature
 94 and flow fields in a lid-driven cavity.

95 Despite the introduction of artificial intelligence, each of the
 96 individual methods still cannot get rid of the fact that none of
 97 them are able to give birth to the desired outcomes because of
 98 their disadvantages. For instance, neural networks attain the results
 99 closer to local ones not the global optimal ones. Expert systems
 100 excessively rely on knowledge and cannot gain the optimal results
 101 all the time while the grey prediction systems are suitable for
 102 exponential growth models. Thus, by considering every method’s
 103 merits, taking full advantage of them, the concept of the hybrid
 104 and combination methods developed rapidly. The thought of the
 105 combined method was first introduced by Bates et al. [23], who
 106 proved that the combined methods were more efficient and easier
 107 than the single ones. In addition, hybrid and combined methods
 108 aggregate the advantages of multiple separate methods. Because
 109 of these advantages, hybrid and combined methods are widely
 110 used in different applications. Xiong et al. [24] proposed a hybrid
 111 method based on the support vector regression with a firefly algo-
 112 rithm to forecast stock price index. Yu et al. [25] used a novel
 113 hybrid structure named MPSO-BP adaptive algorithm by using the
 114 Radial Basis Function Network (RBFN). Tan et al. [26] developed
 115 a combined method by using three individual methods namely
 116 wavelet transform, ARIMA and Generalized Autoregressive Condi-
 117 tional Heteroscedasticity (GARCH) to forecast the electricity price.

118 Although hybrid and combined methods have priorities, they
 119 focus on different aspects. Hybrid methods use a series of methods
 120 to process the data in advance, such as: noise reduction, sea-
 121 sonal adjustment and cluster, while combined methods use weight
 122 coefficients compared with the individual methods which consti-
 123 tute the hybrid methods. In reference to the merits of these two
 124 kinds of methods, this paper proposes a novel combined method
 125 whose advantage is not only linear time series data but also non-
 126 linear time series data can be processed. The combined forecasting
 127 methods are as follows: diff-SARIMA method deals with the linear
 128 data, while BP method and ANFIS method deal with the nonlinear
 129 data. During the parameter optimization process, the DE optimiza-
 130 tion algorithm was utilized to optimize the weight coefficients of
 131 the combined methods. These three methods were used separately
 132 in different applications.

133 The BP neural network is a multilayer feedforward network
 134 using the input-output model mapping relation theory which was
 135 trained by error back propagation algorithm. By using the steepest
 136 grades descent or other methodologies to modulate all the weights
 137 and thresholds of the whole network, after several iterations, the
 138 least sum of square error can be procured. BP, as one of the most
 139 traditional models, was welcomed in many applications. Reliability
 140 forecasting models for electrical distribution systems considering
 141 component failures and planned outages was used based on BP
