## ABSTRACT

The porous  $\text{Mn}_2\text{Co}_1\text{O}_x$  catalysts are prepared by a one-step combustion (CB) method for low temperature de $\text{NO}_x$  process. This catalyst displays an excellent  $\text{NH}_3$ -SCR activity, achieving 100%  $\text{NO}_x$  conversion at 150–300 °C. In addition, the catalyst shows high  $\text{N}_2$  selectivity, wide operating temperature window, high stability, and high  $\text{H}_2\text{O}$  and  $\text{SO}_2$  resistance. The crystalline phase of  $\text{CoMn}_2\text{O}_4$ , porous structure and large specific surface area are beneficial for the de $\text{NO}_x$  activity. The catalyst exists abundant  $\text{Mn}^{4+}$ ,  $\text{Co}^{3+}$  and surface adsorbed oxygen species, which improve the catalyst's redox ability. Plenty of acid sites from the strong interaction of manganese and cobalt oxide enhance the catalyst performance.

## 1. Introduction

Nitrogen oxides emitted from thermal power plants are currently considered as the main sources of a series of environmental issues [1, 2]. Selective catalytic reduction (SCR) with  $\text{NH}_3$  is a well-proven technique to reduce  $\text{NO}_x$  emissions [3]. Nowadays the most widely used catalyst is  $\text{V}_2\text{O}_5\text{-WO}_3(\text{MoO}_3)/\text{TiO}_2$  for  $\text{NO}_x$  control. However, there are some inevitable problems for this catalyst, such as the toxicity of  $\text{VO}_x$ , a relatively narrow temperature window (300–400 °C) and the deactivation caused by dust and  $\text{SO}_2$  [4]. Therefore, it is vital for us to develop the low-temperature SCR catalysts which can be located the downstream of the desulfurizer and the electrostatic precipitator [5,6].

Transition metal (Fe, Cr, Ce, and Mn) oxide catalysts have been explored intensively in the low-temperature SCR reaction [7,8]. Mn-based oxide catalysts with the superiority of unique activities at low temperature and excellent redox properties have received much attention [9–11]. But due to the high sulfur sensitivity of the Mn-based catalysts, which can induce a severe deactivation, researchers have studied modified Mn-based catalysts by doping the other transition metal oxides [7,12]. Chen et al. showed that Mn–Cr mixed oxide catalysts yielded 98.5%  $\text{NO}_x$  conversion and high  $\text{SO}_2$  tolerance at 120 °C because of the formation of  $\text{CrMn}_{1.5}\text{O}_4$  phase [7]. Lian et al. indicated that  $\text{Mn}_2\text{Nb}_1\text{O}_x(500)$  could obtain 94%  $\text{NO}_x$  conversion and 96%  $\text{N}_2$  selectivity at 125 °C [12]. Wan et al. found that the Ni(0.4)– $\text{MnO}_x$  catalyst

showed 85% of NO conversion at 95 °C and 100% from 120 to 240 °C [13]. Although the research obtained some achievements, it is still important to discover new Mn-based catalysts, which have superior catalytic activity, high  $\text{SO}_2$  tolerance and stability.

Cobalt oxides have long been studied widely in the field of catalysts, due to the terrific redox properties and morphology characteristics [14–16]. Previous researches have already noted that the coupling of Mn and Co oxides has improved the catalytic activity for the oxidation of n-hexane [17–18]. But there have been few reports on Mn–Co mixed oxides for SCR of  $\text{NO}_x$  with  $\text{NH}_3$ . In this study, a series of Mn–Co oxide catalysts, prepared by the one-step combustion method, were examined for the de $\text{NO}_x$  performance and they were the potential catalysts for the low temperature de $\text{NO}_x$  process with high resistance to  $\text{SO}_2$  poisoning.

## 2. Experiments

## 2.1. Catalyst preparation

The  $\text{Mn}_2\text{Co}_1\text{O}_x$  catalyst powders were synthesized using a one-step combustion (CB) method [19]. Stoichiometric amounts of  $\text{Mn}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$  (A) and  $\text{Co}(\text{NO}_3)_2 \cdot 6\text{H}_2\text{O}$  (B) (the mole ratio of A and B was 2:1) were used as the metal precursors. Glycine and citric acid were used to assist combustion so that the catalysts can get the porous structure. The detailed process could be found in the Supplementary Data. The obtained oxides were denoted  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB). Pure  $\text{MnO}_x$  and  $\text{CoO}_x$  were also prepared using the same procedure.

For comparison, the  $\text{Mn}_2\text{Co}_1\text{O}_x$  particles were prepared by coprecipitation (CP) method, noted as  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP), according to literature with some modification [20].

## 2.2. Catalyst characterization

The obtained products were characterized by X-ray diffraction (XRD, Rigaku Ultima IV, Cu K $\alpha$  radiation, 40 kV, 40 mA). The morphology was characterized using a scanning electron microscope (SEM, QUANTA FEG 250). The specific surface area and pore size distribution were determined by  $\text{N}_2$  adsorption-desorption measurements at 77 K using a Quantachrome Instrument ASIQU000-1-MP. Prior to  $\text{N}_2$  adsorption, the samples were degassed at 300 °C for 4 h. X-ray photoelectron spectroscopy (XPS) was carried out on a PHI QUANTERA-II from Japan Ulvac-PHI INC using 25 W Al-K $\alpha$  radiation. The binding energies were referred to the C 1s line at 284.8 eV.

$\text{H}_2$  temperature programmed reduction ( $\text{H}_2$ -TPR) and  $\text{NH}_3$  temperature programmed desorption ( $\text{NH}_3$ -TPD) were performed on a Quantachrome Chembet Pulsar. The  $\text{H}_2$  consumption was quantified by a thermal conductivity detector (TCD). Prior to  $\text{H}_2$ -TPR experiment, 50 mg of catalysts was pretreated with He with a total flow rate of 30 mL·min<sup>-1</sup> at 450 °C for 1 h, then heated in 5%  $\text{H}_2$ /Ar (30 mL·min<sup>-1</sup>) from room temperature to 800 °C with a ramping rate of 10 °C·min<sup>-1</sup>. For the  $\text{NH}_3$ -TPD experiments, the catalysts (100 mg) were pretreated at 450 °C for 1 h in flowing He, then was exposed at 80 °C to  $\text{NH}_3$  until saturation followed by purging with He for 30 min to remove adsorbed species. Finally, the reactor temperature was raised to 800 °C at a rate of 10 °C·min<sup>-1</sup> for  $\text{NH}_3$  desorption.

## 2.3. Catalytic activity measurement

The  $\text{NH}_3$ -SCR activity tests were performed in a fixed-bed quartz reactor with an inner diameter of 8 mm under the following condition: 1000 ppm  $\text{NH}_3$ , 1000 ppm  $\text{NO}$ , 5 (vol)%  $\text{O}_2$ , 10 (vol)%  $\text{H}_2\text{O}$  (when used), 100 ppm  $\text{SO}_2$  (when used) and balance  $\text{N}_2$ , 0.3 g catalyst (60–100 mesh), the flow rate was 500 mL·min<sup>-1</sup>, thus the GHSV of 30,000 h<sup>-1</sup> was obtained. The outlet  $\text{NO}_x$  was monitored by a gas analyzer (MRU VARIO PLUS, Germany), the  $\text{NH}_3$  and  $\text{N}_2\text{O}$  were monitored by a Benchtop Gas Analysis System (HPR-20 QIC). From the concentration of the gases at steady state,  $\text{NO}_x$  conversion was calculated according to the following equation:

$$\text{NO}_x \text{ conversion (\%)} = \frac{[\text{NO}_x]_{\text{in}} - [\text{NO}_x]_{\text{out}}}{[\text{NO}_x]_{\text{in}}} \times 100\%$$

The  $\text{N}_2$  selectivity in SCR reaction was calculated according to the following equation [21]:

$$S_{\text{N}_2} = \left( 1 - \frac{2[\text{N}_2\text{O}]_{\text{out}}}{[\text{NO}_x]_{\text{in}} + [\text{NH}_3]_{\text{in}} - [\text{NO}_x]_{\text{out}} - [\text{NH}_3]_{\text{out}}} \right) \times 100\%$$

where  $[\text{NO}_x] = [\text{NO}] + [\text{NO}_2]$ .

## 3. Results and discussion

### 3.1. Low-temperature activity for $\text{NO}_x$ conversion and $\text{N}_2$ selectivity of $\text{Mn}_2\text{Co}_1\text{O}_x$ (CB), $\text{Mn}_2\text{Co}_1\text{O}_x$ (CP), $\text{MnO}_x$ (CB), $\text{CoO}_x$ (CB)

The  $\text{NO}_x$  conversion and  $\text{N}_2$  selectivity of  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB),  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP),  $\text{MnO}_x$  (CB) and  $\text{CoO}_x$  (CB) catalysts are shown in Fig. 1.  $\text{CoO}_x$  (CB) showed negligible activity, but  $\text{MnO}_x$  exhibited a relatively higher catalytic activity of 80%  $\text{NO}_x$  conversion at 200 °C (Fig. 1A).  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) and  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP) catalysts both achieve excellent de $\text{NO}_x$  efficiency, especially for  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB). Meanwhile,  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) had the highest  $\text{N}_2$  selectivity, approximately 100%  $\text{N}_2$  selectivity at 100–250 °C, compared with  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP),  $\text{MnO}_x$  (CB) and  $\text{CoO}_x$  (CB). The  $\text{N}_2$  selectivity of  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) had a tiny decline with temperature increasing, but still remaining 90% at 350 °C; and the  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) catalyst owned the wider operation temperature window compared with  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP), which implies the better catalytic activity for  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) than that of  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP). Compared with  $\text{MnO}_x$  and  $\text{CoO}_x$  catalysts, the outstanding activity for the  $\text{Mn}_2\text{Co}_1\text{O}_x$  catalysts can be due to some synergistic effect between Mn and Co species. Compared with  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP) catalysts, the high catalytic activity of the  $\text{Mn}_2\text{Co}_1\text{O}_x$  catalysts can be owed to the abundant Brønsted and Lewis acid sites, which will be investigated further in the subsequent experiment.

### 3.2. Analysis of XRD, SEM and BET

The XRD patterns of Mn–Co oxide catalysts are depicted in Fig. S1 of the

Supplementary Information (SI).  $\text{MnO}_x$  (CB) and  $\text{CoO}_x$  (CB) samples represent  $\text{Mn}_3\text{O}_4$  and  $\text{Co}_3\text{O}_4$ , and  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) and  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP) catalysts belong to the spinel structure  $\text{CoMn}_2\text{O}_4$ . The  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) catalysts have the higher crystallinity, which may be a reason of the better  $\text{NO}$  conversion of the  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) catalysts.

The SEM images of the  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) and  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP) catalysts are shown in Fig. 2. The  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB) catalysts present polyporous

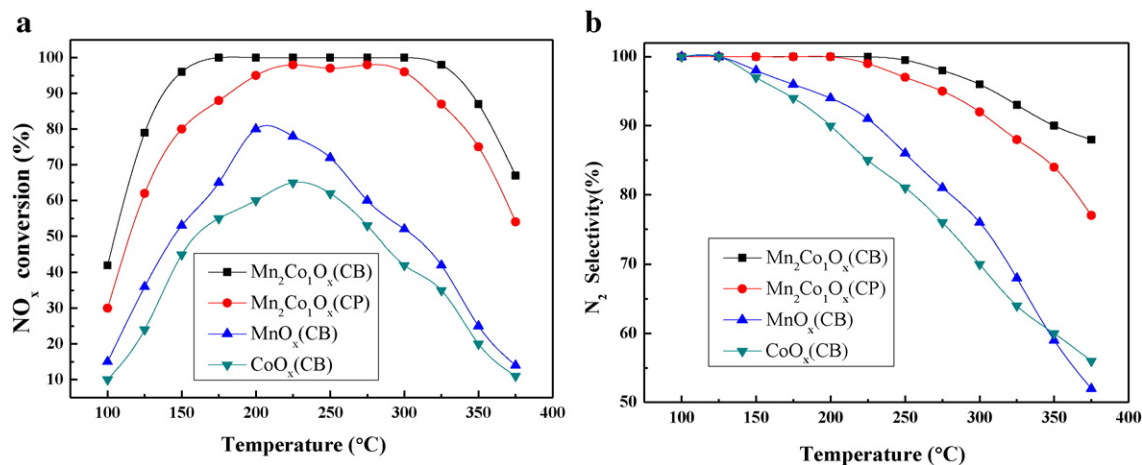

Fig. 1. (A) SCR activity and (B)  $\text{N}_2$  selectivity of  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CB),  $\text{Mn}_2\text{Co}_1\text{O}_x$  (CP),  $\text{MnO}_x$  (CB) and  $\text{CoO}_x$  (CB), calcined at 450 °C. Reaction conditions:  $[\text{NO}] = [\text{NH}_3] = 1000$  ppm,  $[\text{O}_2] = 5$  (vol)%,  $\text{N}_2$  balance, and GHSV = 30,000 h<sup>-1</sup>.
