This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- An implicit diffusion solver is analyzed to predict convergence rates for a range of a damping coefficient.
- The damping coefficient should be $4/3$ or stay close to 1 for better accuracy and iterative convergence.
- Implicit Navier–Stokes solver can diverge for a small damping coefficient even when dominated by convection.
- A variable-preconditioner Newton–Krylov solver is demonstrated as a robust alternative, which converges even when the implicit solver diverges.
