This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- The paper deals with the modeling and stabilization problem for NCSs with packet dropouts and occasionally missing control inputs. In particular, the focus of the paper is to capture the case where the packet dropouts and occasionally missing control inputs are subject to multiple sampling periods, and not periodic as in existing results.
- Input-delay approach is used to deal with the packet dropouts that are subject to multiple sampling periods. Whats more, by employing the probability theory such as the celebrated formula of total probability twice, double randomness of the input delay $d(t)$ caused by multiple sampling periods and packet dropouts can be transformed into randomness of a parameter matrix of the transformed system, and then the corresponding results can be analyzed by making use of switched time-delay system approaches.
- A new stabilization problem is addressed for a class of sampled-data systems where both packet dropouts and occasionally missing control inputs are considered simultaneously. Some quantitative relations are established among some system variables.
