This study considers the finite-time dissipative control problem for a class of discrete stochastic systems under the circumstance of wireless communication networks, in which both randomly occurring uncertainties and stochastic fading measurements are involved. A modified stochastic Rice fading model with *disturbance-dependent Gaussian noise* is put forward to better reflect the fading phenomena in complex wireless communication networks. By introducing a novel concept of *finite-time stochastic exponential dissipative*, this work designs a state-feedback controller such that the closed-loop system is finite-time stochastic bounded with a prescribed exponential dissipativity performance. Moreover, some parameters-dependent sufficient conditions on the existence of the finite-time dissipative controller are derived and the corresponding computation algorithm is given. An numerical example is finally provided to illustrate the effectiveness of the proposed design approach.

**Keywords:** dissipative control; finite-time boundedness; randomly occurring uncertainties; stochastic fading measurements; stochastic systems

## 1. Introduction

In today's pervasive networked environments, more information is transmitted via wired/wireless communication links. Due to limited bandwidth, the network load may randomly fluctuate and the signal transmission may suffer from unpredictable networked-induced phenomena. Among them, in order to cope with the uncertainties of system may occur in a random way, the concept of randomly occurring uncertainties (ROUs) was introduced in [1]. To date, the occurrence of ROUs has gained some particular research interest, see, e.g., [2] and [3]. Meanwhile, another special phenomenon typically induced by wireless communication networks, namely, channel fading, has been paid more and more attentions by many researchers [4–6]. Generally speaking, when a signal is transmitted over a wireless channel, it is inevitably subject to some special physical phenomena
