10 **Abstract**

11 As biomass becomes more integrated into our energy feedstocks, the ability to predict its
12 combustion enthalpies from routine data such as carbon, ash, and moisture content enables rapid
13 decisions about utilization. The present work constructs a novel artificial neural network model
14 with a 3-3-1 tangent sigmoid architecture to predict biomasses' higher heating values from only
15 their proximate analyses, requiring minimal specificity as compared to models based on
16 elemental composition. The model presented has a considerably higher correlation coefficient
17 (0.963) and lower root mean square (0.375), mean absolute (0.328), and mean bias errors (0.010)
18 than other models presented in the literature which, at least when applied to the present data set,
19 tend to under-predict the combustion enthalpy.
