Bipolar plates

Flow field

ABSTRACT

This study investigates flow fields and flow field plates (bipolar plates) in proton exchange membrane fuel cells. In this regard, the main design considerations and limitations for a flow field network have been examined, along with a comprehensive review of currently available flow field channel configurations. Also, the common materials and material properties used for flow field plates have been explored. Furthermore, a case study of step-by-step modeling for an optimum flow field design has been presented in-details. Finally, a parametric study has been conducted with respect to many design and performance parameters in a flow field plate.

1. Introduction

Hydrogen and fuel cell systems are the most important candidates to meet the energy demand in the near future [1]. In the proton exchange membrane (PEM) fuel cells, uniformity of reactants distribution to and inside each individual unit cell is indispensable to obtain optimum performance from the fuel cell stack. The design of the reactants manifold guarantees delivery of reactants to each individual cell, while the flow fields distribute the reactant gasses received from the manifold evenly over the active area of each individual unit cell. Thus, the main function of flow fields is to evenly distribute the reactants to the gas diffusion layer (GDL) and then to the active catalyst layer in the membrane electrode assembly (MEA) through the porous electrode while maintaining a minimum pressure drop [2–7].

Delivery of reactants and removal of products from a PEMFC is crucial for optimum performance and durability. Flow-field design of bipolar plates is the main actor for these processes. Power capacity value of a PEMFC can be affected by the flow field design excessively. Homogeneous current and temperature distribution along with effective water removal are crucial tasks, and require a careful flow field design in a PEMFC.

Fig. 1 illustrates this concept. Bipolar plates, also called flow field plates, constitute more than 60% of the weight and 30% of

the total cost in a fuel cell stack [9]. Table 1 lists the main functions a bipolar plate performs in a PEMFC and the corresponding properties.

The main task of designing a flow field network is to achieve the maximum possible homogeneity over the cell's active area, which means using the hydrogen effectively [10], with respect to temperature, gas concentration, and humidity. The stoichiometry and composition of the reactants and the stack's operating conditions have to be accurately accounted for [11,12]. However, this is not an easy task due to many conflicting design parameters that have opposing effect on the overall fuel cell efficiency. Therefore, the main constraint to an optimum design of a flow field is the complex balance between these parameters [13].

Bipolar plates are counted for around 60% of the total cost of the stack. Also, an optimal design of the bipolar plate can improve the overall stack performance considerably, as high as 50%. Due to these significant importance and their critical roles, in this manuscript bipolar plates have been studied in detail presenting design considerations and constraints, bipolar plate materials, channel configurations, channel-land dimensions and shape, flow directions, pressure drop, heat and mass transfer, as well as electrical conductivity and resistivity.

2. Bipolar plate materials

In order for a bipolar plate to perform the functions listed in Table 1, it must be manufactured from materials with properties that satisfy the necessary requirements.

Nomenclature

$LtoC = \frac{w_l}{w_c}$	land-to-channel ratio	K	permeability of the porous flow field (m^2)
w_l	land width (m)	A_{CS}	cross-sectional area of the flow field (m^2)
w_c	channel width (m)	L	length of the flow field (m)
d_c	channel depth (m)	\dot{N}_{gas}	molar flow rate of the oxidant or fuel
d_{BP}	bipolar plate depth (m)	P_{vap}	partial pressure of the water vapor in the gas stream
d_{GDL}	GDL depth (m)	P_T	total gas pressure (Pa)
$\rho_{BP,z}$	resistivity of the bipolar plate in the z-direction ($\Omega\text{ cm}$)	u_m	mean velocity (m/s)
$\rho_{BP,xy}$	resistivity of the bipolar plate in the xy-plane ($\Omega\text{ cm}$)	H	height of the channel (m)
$\rho_{GDL,z}$	resistivity of the GDL in the z-direction ($\Omega\text{ cm}$)	y_i	central location of each node (m)
$\rho_{GDL,xy}$	resistivity of the GDL in the xy-plane ($\Omega\text{ cm}$)	Δy	distance between adjacent nodes (m)
R_{CR}	contact resistance between the GDL and the bipolar plate ($\Omega\text{ cm}^2$)	N	number of nodes
$I_{density,GDL-CL}$	current density at the GDL-catalyst layer interface (A/cm^2)	c i	specific heat capacity ($J/kg\text{ K}$)
ν	Poisson's ratio	W	depth of the channel (m)
P	pressure (kPa)	T	temperature (K)
E	Young's modulus (kPa)	k	conductivity ($W/m\text{ K}$)
t	thickness of the MEA (mm)	T_s	plate surface temperature (K)
b	unsupported channel width (mm)	$A_{electrode}$	electrode's surface area.
L	channel length (mm)	h_m	mass transfer coefficient.
$(\Delta P)_{parallel}$	pressure drop across a parallel-channel flow field (Pa)	ΔC_{lm}	logarithmic concentration difference
f	friction factor	Sh	Sherwood number
L	channel length (m)	$D_{i,j}$	binary diffusion coefficient for species i and j
D_H	hydraulic diameter (m)	T_{ref}	temperature at which the binary diffusion coefficient is known
ρ	fluid density (kg/m^3)	T	temperature of the reactant
v_{avg}	average velocity (m/s)	$C_{m,in}$	mean concentration at the flow channel inlet
K_L	local resistance found experimentally	$C_{m,out}$	mean concentration at the flow channel outlet
A_{active}	cell active area (m^2)	A_a	apparent contact area between the GDL and the bipolar plate (m^2)
$N_{channels}$	number of parallel channels	K	geometric constant
A_{CS}	cross-sectional area of the channel (m^2)	G	topothesy of a surface profile.
p	wetted perimeter of the channel, (m)	D	fractal dimension of a surface profile
N_{cells}	number of cells	P^*	ratio of the actual clamping pressure and comprehensive modulus of GDL
I	stack current (A)	k	effective electrical conductivity of the two surfaces (S/m)
SO_2	oxygen stoichiometric ratio	ρ	contact resistivity ($\Omega\text{ cm}^2$)
S_{H_2}	hydrogen stoichiometric ratio	P	contact clamping pressure (MPa)
R	universal gas constant, equal to 8.314 ($J/mol\text{ K}$)	A, B, and C	experimental constants
T_{in}	stack's inlet temperature (K)	L	distance between the bypass location to the bypass emergence point
F	Faraday's constant, equal to 96,485 (C/mol)	V	channel bulk flow velocity
P_{in}	stack inlet pressure (Pa)	U_{avg}	bulk average velocity through the GDL
ϕ	relative humidity	ΔS	porous GDL thickness in the flow direction (equivalent to the land width, w_l)
$P_{sat@T_{in}}$	saturation pressure at the given inlet temperature (Pa)	d_h	channel's hydraulic diameter, found (in general and for a rectangular channel, respectively)
r_{H_2}	hydrogen volume fraction in the fuel mixture	A_{CS}	cross-sectional area of the channel
r_{O_2}	oxygen volume fraction in the air mixture	p	wetted perimeter of the channel
$Q_{stack,in}$	stack's inlet volumetric flow rate (m^3/s)	ε	porosity of the porous medium
Re	Reynolds's number	d_s	diameter of the theoretical spherical particles the medium is modeled to consist of (pore diameter)
μ	fluid viscosity, ($kg/m\text{ s}$)		
$\frac{\varepsilon}{D}$	relative roughness (absolute roughness divided by the channel's inner diameter)		
$I_{density}$	current density (A/m^2)		
$(\Delta P)_{porous}$	pressure drop across a porous flow field (Pa)		
Q_{cell}	volumetric flow rate through a cell (m^3/s)		

In general, there are two main families of materials that are commonly used for the production of bipolar plates; graphite and metals. Despite its high cost, solid graphite is commonly used due to its corrosion resistance, chemical inertness and good conductivity. However, their favorableness is decreasing due to the fact that they cannot be mass produced since flow channels need to be machined or electrochemically etched on the graphite bipolar plate surface. In contrast to graphite, metallic plates are suitable for mass production in very thin layers for lightweight and portable stacks. Some of the main material properties of graphite/composite and metallic bipolar plates have been listed in Table 2, respectively.

Metals can dissolve and diffuse into the electrolyte, which is usual in the corrosive environment of the bipolar plates. This process lowers ionic conductivity, and fuel cell's overall efficiency and life. Some materials such as graphite, gold, silver, palladium, platinum, carbon and conductive polymer are used to coat the bipolar plate, and prevent corrosion while promoting conductivity. Common coating concerns are corrosion resistance, micro-pores/cracks and more importantly difference in the thermal expansion coefficient compared to the plate itself.

Table 3 includes common materials used for coatings. These materials are selected based on their conductivity, corrosion resistance, thermal expansion, and the absence of micro-pores/cracks.
