Air-blast response of sacrificial cladding using low density foams:
experimental and analytical approach

H. Ousji, B. Belkassem, M.A. Louar, B. Reymen, J. Martino,
D. Lecompte, L. Pyl, J. Vantomme

PII: S0020-7403(16)30754-8
DOI: [10.1016/j.ijmecsci.2017.05.024](https://doi.org/10.1016/j.ijmecsci.2017.05.024)
Reference: MS 3699

To appear in: *International Journal of Mechanical Sciences*

Received date: 10 November 2016
Revised date: 13 March 2017
Accepted date: 5 May 2017

This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- The study of the effectiveness of the sacrificial cladding and the fluid-structure interaction (FSI) effect to mitigate a given blast load.
- The minimum polyurethane thickness needed to mitigate a given blast load, depends on the blast load, the front plate mass, the plateau stress and the densification strain.
- The analytical model of Hanssen et al. over-estimates the front plate displacement and hence, the minimum polyurethane thickness. While Hanssen et al. use quasi-static plateau stress, it should be noted that the transmitted pressure to the main structure using PU as crushable core, is higher than the plateau stress obtained from quasi-static tests.
- The FSI effect cannot be neglected in the case of low density foam.
- The Kambouchev-Noels-Radovitzky (KNR) theory is suitable to simulate the FSI effect in the case of low density foam.
