9 **Abstract**

10 Prosthesis positioning in transcatheter aortic valve implantation procedures repre-
11 sents a crucial aspect for procedure success as demonstrated by many recent studies on
12 this topic. Possible complications, device performance, and, consequently, also long-term
13 durability are highly affected by the adopted prosthesis placement strategy. In the present
14 work, we develop a computational finite element model able to predict device-specific and
15 patient-specific replacement procedure outcomes, which may help medical operators to
16 plan and choose the optimal implantation strategy. We focus in particular on the effects
17 of prosthesis implantation depth and release angle. We start from a real clinical case
18 undergoing Corevalve self-expanding device implantation. Our study confirms the crucial
19 role of positioning in determining valve anchoring, replacement failure due to intra or
20 para-valvular regurgitation, and post-operative device deformation.

21 **1 Introduction**

22 The first transcatheter aortic valve implantation (TAVI) dates back to 2002 [7]. Since then,
23 many studies have demonstrated the efficacy of such a minimally-invasive approach for the
